In the *Phil. Mag.* for July, 1889, Prof. J. J. Thomson has examined this question. Like myself, he fails to find a solution within the cone; but concludes that the displacement is confined to its surface. If so, it must form, along with the magnetic induction, an electromagnetic wave. But it may be readily seen that such a wave is impossible, having no stability.

For as the charge moves from A to B, a given surface element, C, would move to D. In doing so its area would vary directly as its distance from the apex, and the energy in the element would therefore vary inversely as its distance from the apex, and the forces, electric and magnetic, would therefore vary inversely as the square root of the distance from the apex, instead of inversely as the distance, which is obviously necessary in order that the displacement may be confined to the surface. This conflict of conditions constitutes instability. In the *Phil. Mag.* for April I suggested that whilst there must be a solution of some kind, one representing a *steady* state was impossible. This conclusion is confirmed by the failure of Prof. Thomson's proposed surface wave to keep itself going.

Prof. Thomson, who otherwise confirms my results, has also extended the matter by supposing that the medium itself is set in motion, as well as the electrification. This is somewhat beyond me. I do not yet know certainly that the ether can move, or its laws of motion if it can. Fresnel thought the earth could move through the ether without disturbing it; Stokes, that it carried the ether along with it, by giving irrotational motion to it. Perhaps the truth is between the two. Then there is the possibility of holes in the ether, as suggested by a German philosopher. When we get into one of these holes, we go out of existence. It is a splendid idea, but experimental evidence is much wanting.

But if we consider that the medium supporting the electric and magnetic fluxes is really set moving when a body moves, and assume a particular kind of motion, it is certainly an in-

Digitized by Google

teresting scientific question to ask what influence the motion exerts on the electro-magnetic phenomena. I do not, however, think that any new principles are involved.

The general connections of **E** and **H**, referred to fixed space without conductivity being

$$\text{curl}\,(\mathbf{e}-\mathbf{E})=\mu p\mathbf{H}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$\text{curl}\,(\mathbf{H}-\mathbf{h})=cp\mathbf{E}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where p stands for d/dt and **e** and **h** are the impressed parts of **E** and **H**; if there is also motion of electrification, we have to consider it to constitute a convection-current, a part of the true current, and so make (2) become

$$\text{curl}\,(\mathbf{H}-\mathbf{h})=cp\mathbf{E}+4\pi\rho\mathbf{u} \quad . \quad . \quad . \quad . \quad (3)$$

where ρ is the density of electrification, whose velocity is **u**. (See *The Electrician*, November 23, 1888, p. 83). It now remains to specify **e** and **h**. They are zero when the medium supporting the fluxes is at rest. But if it moves, and its velocity is **w**, there is, first, the electric force due to motion in a magnetic field,

$$\mathbf{e}=\mu\mathrm{V}\mathbf{w}\mathbf{H} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

which is well known; and next the magnetic force due to motion in an electric field,

$$\mathbf{h}=c\mathrm{V}\mathbf{E}\mathbf{w} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

which is not so well known. [First, I believe, given by me in the third section of "Electromagnetic Induction and its Propagation," *The Electrician*, January 24, 1885; again, obtained in a different way in section XXII., January 15, 1886; *see* also *Phil Mag.*, August, 1886, and an example of the use of (4) and (5) in *The Electrician*, April 12, 1889, p. 683.]

The mechanical force called by Maxwell the "electro-magnetic force" is $\mathrm{V}\mathbf{C}\mathbf{B}$, where **C** is the true current and **B** the induction. It is the force on the matter supporting electric current. Let it move. If **w** is its velocity the activity of the field is

$$\mathbf{w}\mathrm{V}\mathbf{C}\mathbf{B}=\mathbf{C}\mathrm{V}\mathbf{B}\mathbf{w}=-\mathbf{e}\mathbf{C} \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Similarly, as I obtained in Section XXII. above referred to, there is a mechanical force (the magneto-electric) on matter supporting magnetic current $\mathfrak{G}=\mu p\mathbf{H}/4\pi$, expressed by $4\pi\mathrm{V}\mathbf{D}\mathfrak{G}$, and its activity is

$$4\pi\mathbf{w}\mathrm{V}\mathbf{D}\mathfrak{G}=4\pi\mathfrak{G}\mathrm{V}\mathbf{w}\mathbf{D}=-\mathbf{h}\mathfrak{G} \quad . \quad . \quad . \quad (7)$$

Of course **e** and **h** are impressed forces, which is the reason of the change of sign. *Their* activities are $\mathbf{e}\mathbf{C}$ and $\mathbf{h}\mathfrak{G}$.

It should be remarked further, that the above expressions for **e** and **h** are not *certain*. For I have shown that the sources of all disturbances are the lines of curl of the impressed forces (*Phil. Mag.*, Dec., 1887), and that the fluxes produced depend solely upon the curls of **e** and **h**, both as regards the steady fluxes and the variable ones leading to them. We may, therefore, use any other expressions for **e** and **h** which have the same curls as the above. And, in fact, we see that equations (1) and (2) only contain their curls.

Equations (1) and (3), with **e** and **h** defined by (4) and (5) therefore enable us to determine the effect of the moving medium. Prof. Thomson also arrives at (4) and (5), and at the "magneto-electric force," in his Paper to which I have referred, by an entirely different method. And to show how well things fit together, he concludes, from the consideration of the moving medium, that a moving electrified surface is a current sheet, which is another way of saying that a convection current is a part of the true current, as expressed in (3). I must however disagree with Prof. Thomson's assumption that the motion must be irrotational. It would appear, by the above, that this limitation is unnecessary.

As an example, and to introduce a new point, take the case of a charge q moving at speed u along the axis of z. It will come to the same thing if we keep the charge at rest, and move the medium the other way. We then use the equations (1) and (2), and in them use (4) and (5) with $\mathbf{w}=-\mathbf{u}$. Now when the steady state is arrived at, we have $p=0$, so (1) and (2) become

$$\text{curl}\,(\mu\mathrm{V}\mathbf{H}\mathbf{u}-\mathbf{E})=0, \quad . \quad . \quad . \quad . \quad (8)$$

$$\text{curl}\,(\mathbf{H}-c\mathrm{V}\mathbf{u}\mathbf{E})=0, \quad . \quad . \quad . \quad . \quad (9)$$

In addition, the divergence of **D** must be q at the origin, and the divergence of **B** must be zero. The latter gives, applied to (9)

$$\mathbf{H}=c\mathrm{V}\mathbf{u}\mathbf{E}, \quad . \quad . \quad . \quad . \quad . \quad (10)$$

which gives **H** fully in terms of **E**. Eliminate **H** from (8) by means of (10) and we get

$$\text{curl}\,(\mu c\mathrm{V}\mathbf{u}\mathrm{V}\mathbf{E}\mathbf{u}-\mathbf{E})=0, \quad . \quad . \quad . \quad (11)$$

or

$$\text{curl}\left[\frac{u^2}{v^2}(\mathbf{E}-\mathrm{E}_3\mathbf{k})-\mathbf{E}\right]=0 \quad . \quad . \quad . \quad (12)$$

where E_3 is the z component of **E** and **k** a unit vector along z; or, integrating, and writing the three components,

$$\mathrm{E}_1=-\frac{d\mathrm{P}}{dx}, \quad \mathrm{E}_2=-\frac{d\mathrm{P}}{dy}, \quad \mathrm{E}_3=-\left(1-\frac{u^2}{v^2}\right)\frac{d\mathrm{P}}{dz}, \quad (13)$$

where P is a scalar potential; here is the new point. There *is* a potential, of a peculiar kind. The displacement due to the moving charge is distributed in precisely the same way as if it were at rest in an eolotropic medium, whose permittivity is c in all directions transverse to the line of motion, but is smaller, viz., $c(1-u^2/v^2)$, along that line and parallel to it. The potential P is given by

$$\mathrm{P}=\frac{q}{c\left[(x^2+y^2)(1-u^2/v^2)+z^2\right]^{\frac{1}{2}}} \quad . \quad . \quad . \quad (14)$$

It is a particular case of eolotropy with c_1, c_2, c_3, the principal permittivities, all unequal. Thus, with q at the origin, the potential is

$$\mathrm{P}=\frac{q}{(c_1c_2c_3)^{\frac{1}{2}}\left(\frac{x^2}{c_1}+\frac{y^2}{c_2}+\frac{z^2}{c_3}\right)^{\frac{1}{2}}} \quad . \quad . \quad . \quad (15)$$

Observe that although the electric force in the substituted problem of a charge at rest in an eolotropic medium is the slope of a potential; yet it is not so when the medium is isotropic, and moves past the fixed charge, or *vice versâ*, although the distributions of displacement are the same.

When $u=v$ we abolish the permittivity along the z-axis in the substituted case, so that the displacement must be wholly transverse. We then have the plane electromagnetic wave. When u is greater than v it makes the permittivity negative along z; this is an impossible electrical problem, and furnishes another reason for supposing that there can be no steady state in the corresponding electromagnetic problem.

It now remains to find what *would* happen if electrification were conveyed through a medium faster than the natural speed of propagation of disturbances. There is the cone; but what takes place within it?—Yours, &c., OLIVER HEAVISIDE.

Aug. 25, 1889.

THE THEORY OF ALTERNATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The writers of the interesting letters which have lately appeared in your columns raise many points on which I should like to comment, but at present I have not time to deal with the matter in any detail. I may say, however, that in my opinion the points which may have been overlooked or misunderstood by some of your correspondents have been very clearly indicated in your editorial remarks.

It appears to have been thought that because I did not give many details of actual tests the views expressed in my Paper were founded on very incomplete information. As a matter of fact, the Paper was so long that I had not space to record the particulars of the tests, and had to content myself by stating the general conclusions to which the experiments pointed.—Yours, &c., W. M. MORDEY.

London, Sept. 3, 1889.

"AN IMPROVED LIGHTNING PROTECTOR."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Absence has until now prevented me from seeing the letters on this subject in your issue of August 23rd. In the article suggesting the adoption of a fine wire coil in intimate

Digitized by Google

association with an earthed cylinder, I was particularly careful to say that such an arrangement was novel, *so far as I was aware*, because it seemed improbable, in spite of the fact that I did not remember to have seen it proposed, that such an obvious and simple device could have been overlooked by electricians devoting special attention (which until recently I had not done) to lightning protection. I am consequently neither surprised nor annoyed to learn that the idea had occurred to Mr. Jamieson, whose discharger, as described in Messrs. Clark, Muirhead, and Co.'s letter, appears to me to possess very considerable merit. It embodies the feature which direct observation over a considerable period on instruments that accidentally contained it has shown to act with remarkable regularity in discharging lightning. My suggestion was the direct outcome of this experience. With regard to Mr. Noble, I can only regret that the results of our experience do not agree better. My statement (to which I completely adhere) about translator coils was made partly on the evidence of my own senses and partly on reports from officials having to do with them, including one from a mechanic who has the duty of re-winding fused instruments. The assertion that the suggested protector is identical with the discarded bobbin protector of the Post-office may be true, for I do not know what that protector was like; but judging from the inaccurate character of several of Mr. Noble's concluding remarks, I think it more likely to be not. For instance, the necessity of protecting serrated dischargers from dust is wholly imaginary. The efficiency of the plate discharger is *not* greater than that of a good serrated one, while in damp situations the plate is more liable to cause leakage. Post-office cables are not invariably protected in the elaborate manner set forth.—I am, &c.,

A. R. BENNETT.

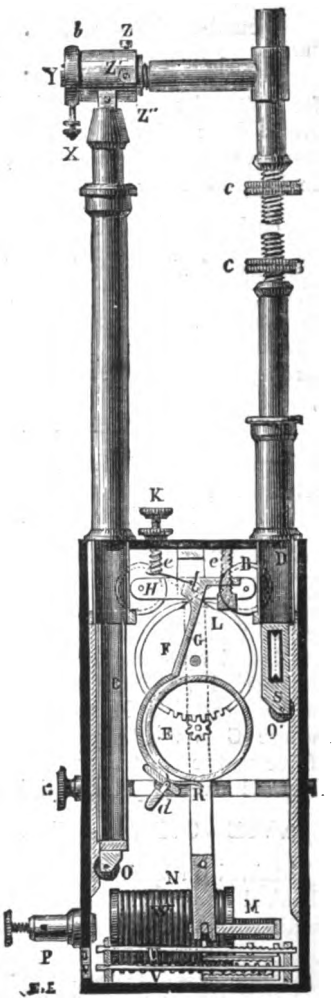
THE HAUCK ARC LAMP.*

The Hauck lamp is self-focussing. The two carbon-holders, C and D are connected by an endless cord, which starts from O, passes over the pulley H, round the wheel L, and over the pulleys



B and S to O', whence it is finally taken to the upper plate of the framework. Whenever the wheel L is free, the weight of the positive rod is sufficient to cause it to slide downwards and pull up the negative rod. But when the wheel L is braked the friction of the endless cord is so great that the whole mechanism is kept

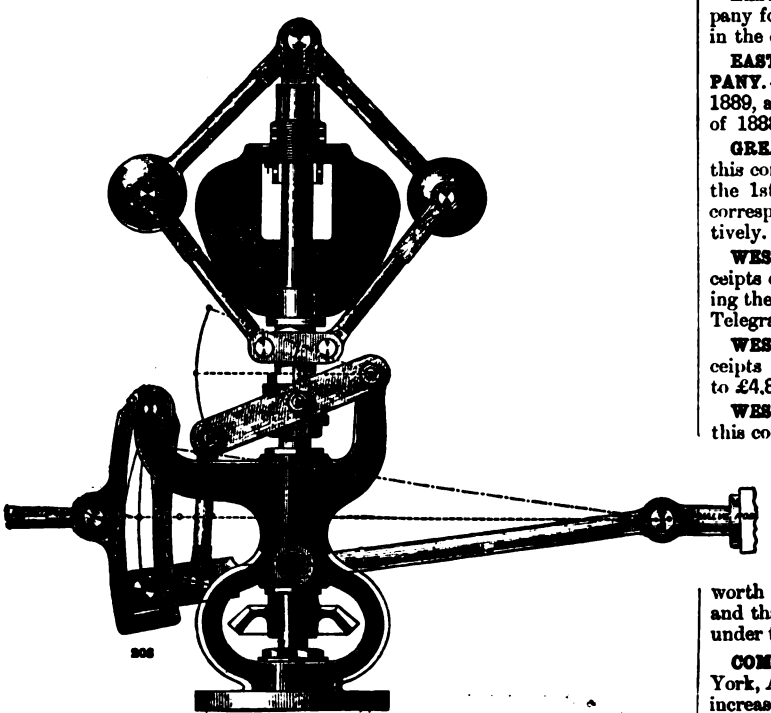
motionless. The pulleys H and B are placed at the end of a T-shaped piece, G, which oscillates round the point *j*, and terminates in a sort of stirrup attached to M, the armature of the solenoid W. The armature M is kept in position by the horizontal spring V, the tension of which can be accurately regulated. The solenoid W is wound with thick wire, and is traversed by the entire current. A brake wheel, E, is mounted on the arm G, and on the axis of E there is a small pinion, engaging with the wheel F, which is furnished with teeth along a certain portion of its circumference. The upper end of the brake rod is bent flat; it is secured by the screw *e*, and kept in a regulated position by means of a spring adjustable at K.

When the current passes through the lamp the armature M is attracted by the solenoid, and G moves round, raising the pulley H, lowering the pulley B, and braking the wheel E. When the current weakens the spring V pulls back the armature M, and the wheel E is freed. The positive carbon-holder descends and the negative carbon-holder is pulled up, the result of these two movements being to diminish the length of the arc.

By means of the screw *a* acting on *d* the wheel E can be braked whenever required. The length of arc is limited by the screw V. The strip R is arranged so as to check the movement of E whenever it becomes too rapid. The upper carbon-holder can be adjusted by means of a series of screws, L, L′, L″, X, Y and *b*, until the carbons are exactly in line.

A NEW GOVERNOR FOR ELECTRIC LIGHT ENGINES.

The illustration given herewith shows a new form of governor recently introduced by Messrs. Clayton and Shuttleworth, the well-known engineers, of Lincoln, which will commend itself for its simplicity, fewness of wearing parts, and efficiency. As the speed of the engine tends to increase, the governor balls and central weight rise, lifting the die in the link and cutting off the steam earlier by thus automatically reducing the travel of the cut-off valve.



The movements of the new governor are regulated as follows: On the vertical spindle is screwed a small piston, accurately fitting a brass-lined cylindrical recess in the central weight, the result being that as this weight rises, the air occupying the space between the bottom of the cylinder and the piston is compressed, thus giving the resistance required to prevent oscillation without the aid of unsightly springs and dashpots. The governor is so proportioned as to be nearly isochronous, and repeated experiments have proved that engines fitted with this expansion gear run at practically the same speed under the most extreme variations of load.

For electric lighting purposes in particular this governor will be found to be well worthy of the careful attention of our readers.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended August 30, 1889, amounted to £4,877.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of August, 1889, were £2,700, as compared with £2,860 in the corresponding month of last year. The receipts for the month of May, estimated at £3,500, realised £3,513.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of August, 1889, amounted to £1,624, as compared with £1,643 last year.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of August, 1889, amounted to £52,012, and to £43,703 in the corresponding period of 1888.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of August, 1889, amounted to £39,469, and to £38,103 in the corresponding period of 1888.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company for the month of August, 1889, amounted to £24,000. From the 1st January to 31st August, 1889, they were £178,200, against, in the corresponding months of 1888 and 1887, £179,200 and £174,120 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended August 30, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,622.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this company for the month ended 31st August, 1889, amounted to £4,850.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this company for the half-month ending August 31 amounted to £2,118, as compared with £2,520 in the corresponding period last year. The May receipts, estimated at £6,219, realised £6,203.

BANKRUPTCY.—In Friday's *Gazette* the bankruptcy was announced of E. Liversedge, electrical engineer, of Huddersfield.

CHANGE OF NAME.—We are informed by Messrs. Charlesworth and Co. that they have made a change in the name of their firm and that henceforth they will carry on the business of electrical engineers under the style of "Charlesworth, Hall and Co."

COMMERCIAL CABLE COMPANY.—A Reuter's telegram, dated New York, August 31, announces that this company has filed a notice of the increase of its capital from 6,000,000 to 10,000,000 dollars.

NATIONAL TELEPHONE COMPANY (LIMITED).—Application has been made to the Committee of the Stock Exchange for a quotation for shares in this company (Nos. 1 to 386,375), in lieu of those of the United Company.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

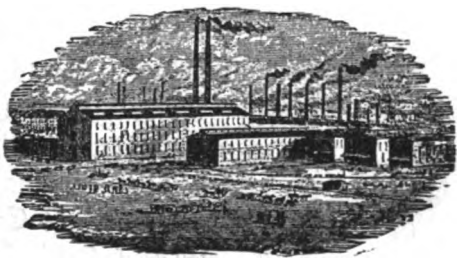
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 56ft. 6in. by 28ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 591.—Vol. XXIII. FRIDAY, SEPTEMBER 13, 1889. Price Fourpence.

NOTES.

The fifty-ninth annual meeting of the British Association was opened at Newcastle-on-Tyne on Wednesday evening. Sir Frederick Bramwell, F.R.S., the retiring President, introduced his successor, Prof. Flower, F.R.S., who delivered an address on "The Practical Organisation of Natural History Museums." Over 3,000 persons were present, and an enthusiastic reception was given to the new President. So far it would appear that the general attendance is likely to exceed that of last year; the number of physicists present is, however, about the same—that is, rather below the average. The Local Committee has spared no trouble to ensure the comfort and convenience of the visitors, and has succeeded in housing the whole of the Sections within a comparatively small area. Section A is excellently bestowed at the College of Science, whilst Section G makes shift with a Presbyterian Church.

Yesterday (Thursday) morning was, as usual, devoted to the Presidential addresses in the Sections, and, as we have previously intimated, the proceedings do not possess any direct interest for our readers. None of the Papers read in the afternoon in Sections A and G related to electricity.

The exceeding crudity of our existing appliances for the manufacture of light is an unfortunate fact with which Dr. Oliver Lodge has by this time made us all fairly familiar. (Or, if there be any who are not yet prepared to subscribe to this, they may be referred to the Lecture on "The Modern Theory of Light," which appeared in our last number). In the absence—so far at least as is generally known—of any very promising line of experimental research on behalf of a method of obtaining luminous vibration unaccompanied by its lower octaves, it is satisfactory to learn that no less a personage than Prof. E. Wiedemann is engaged upon a theoretical investigation of the general subject, with a view also of determining experimentally the numerical values of the quantities involved. Prof. Wiedemann had indeed written something on this question as long ago as 1878, and he has since then referred to it more than once. The current number of the *Phil. Mag.* contains, however, the first instalment of a Paper which is surely destined to become a classic, and to which we must refer those of our readers who wish to follow up the subject. All we can say here is that Prof. Wiedemann gives the name "luminescence" to the phenomena of a body radiating light waves at a temperature which corresponds only to greater wave lengths, and he shows that the phenomena is more frequent than is usually supposed. Luminescence includes all such cases as phosphorescence, fluorescence, vacuum-tube discharges, as well as cases of chemical action, including many instances of flame.

Prof. Wiedemann's theory may perhaps be crudely indicated in a few words. In the case of a gas at a given temperature and pressure, its total energy, according to the usual hypothesis, is distributed according to a fixed and perfectly definite ratio betwixt the internal vibrations of its molecules and their motions of translation. If this were not so, there could be no condition of equilibrium. If, however, the molecules be subject to certain kinds of periodic disturbance, the equilibrium between the two kinds of molecular motion may be upset. The balance tends to restore itself as soon as the exciting cause is withdrawn; but meanwhile, if the internal movements have been augmented at the expense of the external, we should have the phenomenon of luminescence. Similar views, with due restrictions, are applied to solids, and it is shown that if the restoration of balance does not appreciably commence until the excitation is withdrawn, we get what we call phosphorescence; if it proceeds concurrently we have fluorescence. It would certainly appear that in the hands of Prof. Wiedemann this theory is at the very least destined to throw further light upon the nature of Geissler-tube phenomena.

In connection with the contract for the central lighting station at Les Halles, which is still under negotiation by the Paris Municipal Council, some official tests were recently carried out by Messrs. Potier and Carpentier on a new alternator, designed and constructed by MM. Dandeu and Naze. Their report was very unfavourable, the machine, constructed for an output of 220,000 watts, being alleged to heat unduly with a load of only 60,000 watts. On receiving this report an order for Ferranti plant was immediately confirmed. This issue has called forth a most vehement and rhetorical protest from MM. Dandeu and Naze, in which they impeach the *bona fides* of the experiments carried out by MM. Potier and Carpentier, and denounce the Council for lending itself to the introduction of English plant. The Council had already resolved that all the material must be manufactured in France, and the Ferranti machines are supposed to have been built at Cail, but this is stoutly denied by MM. Dandeu and Naze. These gentlemen have also a good deal to say about transformer patents, and the inhuman persecution of the late M. Gaulard. Their position will be

Digitized by Google

better understood if we mention that the central lighting station at Tours, erected in 1885, was carried out by them in conjunction with Messrs. GAULARD and GIBBS. It was a series-system hand regulated, but we believe it has since been changed to parallel.

A CORRESPONDENT writes as follows:—"I met in Paris a few days since an American who had thrown himself into a state of considerable excitement over 'EDISON'S latest invention'—'A Telephone, Sir, which transmits at the rate of 7,428 words per minute.' Certainly the statement did appear with all due gravity in the copy of *Le Temps* which he handed me, but when I had remarked that it would probably require about eight men and a boy to listen at the aforesaid rate, my friend seemed dimly to perceive that there must be something wrong somewhere."

THIS amusing mistake arose, as may easily be supposed, from the substitution of the word telephone for telegraph. But, even so, many of our readers will be surprised to learn that any telegraph apparatus exists capable of working at the rate of over 7,000 words per minute. At the Edison stand in the Paris Exhibition there is, however, an instrument bearing an inscription to the effect that on a date mentioned 7,428 words were transmitted by its agency, over five wires, between New York and Philadelphia. Even when allowance is made for the number of wires employed, we take it that this is the most remarkable feat of rapid telegraphy ever yet accomplished. If we are mistaken in this we should be glad to be corrected.

WE much regret to note that the divergence of opinion which has lately developed itself in the ranks of the NATIONAL (U.S.) ELECTRIC LIGHT ASSOCIATION has culminated in a quarrel whose virulence seems almost to threaten the continued existence of the Association, and has, at any rate, utterly demolished for the time being the dignity and credit of a large number of its members. Amidst the hurricane of denunciation it is a little difficult for an Englishman to make out precisely what the uproar is about. Such terms as "discreditable," "unscrupulous," "unprincipled trickster," "wrecker," "pirate," &c., &c., seem to have been liberally employed, especially in the editorial columns of one at least of their representative journals. Probably, however, compliments of this kind are taken less to heart and inflict less injury, whether upon the originator or the recipient, than would be the case with ourselves; if so, it would be, of course, a mistake to attach too much importance to the episode. So far as we can make out, the trouble had its origin in the introduction, some time since, of a class of Associate Members, who were not necessarily electric lighting men, but were usually connected with the trade in fittings. The presence of these individuals has from the first been a source of offence to a certain section, and they appear to have succeeded in carrying an amendment to the constitution which would ultimately have had the effect of altogether excluding this class from the Association. Naturally this was not accomplished without giving rise to much ill-feeling; the storm did not, however, break out then and there, the President (Mr. WEEKS) ruling, as might have been expected, that the change would not come into operation until the end of the fiscal year. It appears also to have been understood by many members that the resolution would have been submitted for confirmation before it became finally operative. However, on the following day, on the question of the locality where the next meeting should be held, the President remarked that *the new constitution being now in force he could not accept the votes of Associates.* This decision was opportunely delayed until after the votes had been taken, when it appeared that the exclusion of the Associates' vote would reverse the decision of the actual majority in favour of the locality whose claims happened to be supported by the President himself. It was then the row began.

THESE unhappy incidents may at some future day serve the purpose of a useful object lesson for ourselves. It seems likely enough that when the 474 central lighting stations now promised us are in operation somebody will begin to talk about having an Electric Lighting Association in this country. If, however, we are willing to profit by the experience of others, we shall know that the most sensible advice to give is—Don't. If, however, the rash experiment must still be tried, the next lesson would appear to be that dealers in electrical supplies should be rigidly excluded from the first. Lastly, we learn that in the choice of a Chairman it is well, if possible, to discover an individual who possesses the faculty of knowing his own mind.

A SECOND, and in some respects an even graver, scandal is occupying the attention of the American press. Our New York correspondent tells the story of "The Rise and Fall of HAROLD P. BROWN" so concisely that we do not need to recapitulate it here. We would, however, express the earnest hope that this exposure may lead to the repeal of the electrical execution law which the State of New York has been so ill-advised as to adopt.

Lancaster.—At the last meeting of the Lancaster Town Council it was decided to apply for an electric lighting Provisional Order.

The Electric Light at Drury Lane.—Drury Lane Theatre, which is at present undergoing extensive alterations, will be lit throughout by electricity.

Levenshulme.—At Levenshulme, a Manchester suburb, the Local Board decided last week to support the company who are applying for an Order for their district.

Lyons.—The Lyons Gas Company, which some little time ago embarked in the electric lighting business, is about to increase its plant capacity by 5,000 lights.

Ilkeston.—The Town Council at its last meeting unanimously agreed to oppose the application of the Midland House-to-House Electricity Company for a Provisional Order.

Royal College of Science, Dublin.—Particulars of the 1889-90 session of this college will be found in our advertisement columns. The session commences on the 7th October.

Stoke-on-Trent.—The Stoke-on-Trent Town Council, on the recommendation of the Parliamentary Committee, has resolved to oppose the introduction of any Bills dealing with electric lighting in the borough.

The Eiffel Tower.—The telegraphic apparatus upon the top of the Eiffel Tower was inaugurated on Monday morning last, and the first telegram transmitted by it was that of the Paris correspondent of the *Times*.

Digitized by Google

The General Electric Company.—This company has secured the contract to supply all the electrical fittings, &c. (with the exception of the larger electroliers) for the installation of the electric light in the Government House at Shanghai.

Deaths from Lightning in France.—According to recent statistics, 653 people were killed in France from 1852 to 1882 by lightning. Of these, 487 were men and 166 were women. The majority of the deaths occurred in the open fields.

Adoption of the New Police Signal System.—The experiments with a new police signal system at Islington have resulted in its adoption by the Government. It is expected that the system will be extended to other parts of the metropolis.

Obituary.—The death is announced of Dr. Robert von Helmholtz at the early age of 28. The son of a distinguished father, he had already contributed a number of useful Papers to the scientific storehouse, most of them of practical value in meteorology.

Bacup.—The Corporation of Bacup have decided to oppose the application of the Lancashire and Cheshire House-to-House Electricity Company and the Municipal Electric Light and Power Corporation for Provisional Orders for the lighting of the borough.

The Electro-Harmonic Society.—We are requested by the honorary secretary to inform members that should their communications to him not receive the usual prompt reply, it will be in consequence of his absence from home during the meeting of the British Association.

Finsbury Technical College.—The courses of instruction of this college commence on October 8. Several scholarships, all tenable for two years, will be awarded on the results of the entrance examination. Further particulars will be found in our advertisement columns.

Harrogate.—A deputation waited upon the Corporation on Monday with a view of laying before them the advisability of lighting Harrogate by electricity, and of their intention, providing the Council agreed to the project, of seeking Parliamentary powers to accomplish it.

Sheffield.—The application from the Sheffield Telephone Exchange and Electric Light Company for the support of the Sheffield Corporation to their application to the Board of Trade for a Provisional Order will be considered at a special meeting of the Town Council on the 25th inst.

Brighton.—At a meeting of the Town Council last week the recommendations of the Pavilion Committee with regard to the electric lighting of that building, involving an expenditure of £544 for a set of 60 storage cells and alterations to the engine house, were adopted after a lengthy discussion.

Royal Cornwall Polytechnic Society. — The fifty-seventh annual Exhibition of this Society opened on Tuesday last. Several minor electrical exhibits were shown by Mr. W. H. Perrow, of Truro, Mr. W. G. Corse, of Devonport, Messrs. Cathcart and Peto, of London, and Mr. Barnicoat, of Northampton.

Tenders Wanted.—The Receiver for the Metropolitan Police district invites tenders for supplying, fixing, and maintaining electric cell calls at police stations for a period of three years from 1st October, 1889. Tenders must be sent in by the 21st inst. Further particulars will be found in our advertisement columns.

Repair of the Brest-St. Pierre Cable.—We are informed that the cable between Brest (France), and St. Pierre (Miquelon), laid in 1869, and broken in deep water on the 17th July last, was successfully repaired on the 5th instant by the company's steamship "Minia," Captain Trott, commander, and is now working well.

The Electric Light in Spain.—Barcelona advices state that the Gerona firm of Planas, Flaquer and Co., who were charged with the erection of the installation at Pamplona, have been instructed to supply Albacete and Teruel with a similar system of electric light. The Pamplona installation is reported to have given complete satisfaction.

Hawick.—The Town Council, by a majority of 10 to 3, have decided to support the application of the Scottish House-to-House Electricity Company on condition that the price of supply is moderate, that the works are substantial, and that the Council have the option of purchasing the whole concern at the end of every seven years at valuation.

Electric Traction at Florence.—The electric tramway between Florence and the neighbouring town of Fiesole is nearing completion. Its total length is about six miles, of which half consists of 7 per cent. gradients. The rails proceed along the common highway between the two towns. The system adopted is the Sprague with overhead conductors.

Military Telegraphy.—According to the *Bulletin International de l'Electricité* experiments will be carried out at the approaching manœuvres with a new telegraphic appliance. By the aid of an apparatus, which although structurally complicated is easy to manipulate, attempts will be made to reproduce at a distance drawings, plans, or rough maps.

Blackburn.—At a recent meeting of the Gas Committee of the Town Council, it was resolved that it be a recommendation to the Council to instruct the Parliamentary Committee to apply for a Provisional Order empowering the Corporation to supply electricity within the borough for public and private purposes on the lines of the Swansea Electric Lighting Order.

Electric Light Leads.—We have received from the Telegraph Manufacturing Company, of Helsby, some samples of their electric light leads, some of which are insulated with vulcanised and some with pure rubber. The samples range in size from a 19/12 to 1/20 cable, and are neatly secured in a red cloth case, which folds up compactly into the shape of a book.

Sales by Auction.—Our advertisement pages contain particulars of several sales by auction, the dates for which are close at hand. The two sales by Messrs. Wheatley Kirk, Price and Goulty take place on September 18th and 24th, and the sale of the London Stock of electrical fittings, &c., of Messrs. Winfields (Limited) by Mr. Scamell takes place on Monday next, the 16th inst.

Burton-on-Trent.—The Gas Committee of the Burton-on-Trent Town Council intimated, on Wednesday last week, that the manager's report as to the lighting of a portion of the borough by electricity had been laid before them, and they recommended that a statutory meeting of the Council should be held to consider the whole question of electric lighting. The report was adopted.

Birds Destroyed by Electricity.—At the recent meeting of the Zoological Society of France, M.M. Vian, Billard, and Petit presented a report on the subject of the wholesale destruction of swallows by electricity. In the South of France it seems that long wires are systematically erected along the seashore, and when the tired swallows alight on them they are stunned or killed by an electric shock.

A New Insulating Substance.—A by-product resulting from the treatment of asphalte with sulphuric acid, which has hitherto been considered of no value, has, says *La Lumière Electrique*, been found to furnish an excellent insulating material. This substance, which resembles ordinary asphalte, becomes, after exposure to great heat, as hard as ebonite or vulcanite, and possesses high insulating properties.

University College, Bristol.—The calendar of this institution, which is a compendious volume of over 200 pages, contains ample information with regard to the various classes and courses at the College. During the first and second terms Prof. J. Ryan will give a course of 20 evening popular lectures on "Electricity and Magnetism," as well as a systematic course of instruction in electrical laboratory work during the same period.

The Congress of German Naturalists.—The Congress of the German Naturalists (the equivalent of our British Association) is to be held in Heidelberg from September 18th to the 22nd. Simultaneously with the Congress there will be an exhibition of scientific apparatus, instruments, and preparations in the Gymnastic Hall of the town. Amongst the numerous Papers to be read is one by Hertz, on "The Relations between Light and Electricity."

Digitized by Google

Edinburgh.—At a meeting of the Town Council on Monday, the notices of the proposed applications by the electric lighting companies for powers to light the city by electricity were considered. Lord Provost Boyd moved that the Council refuse their consent to the applications and remit the questions generally to the Lord Provost's Committee with powers to support any action that might be taken by the Gas Commissioners. The motion was adopted.

Reorganisation of the London Telephone Staff.—Owing to the new arrangements consequent upon the amalgamation of the telephone companies, Mrs. Beaufoy Merlin, who nine years ago started and organised the staff of ladies belonging to the service of the United Telephone Company, has resigned, and upon her retirement she was presented with a very handsome gold bracelet, and an address expressing the high esteem in which she was held by the large staff under her superintendence.

Mr. Edison in Paris.—The Town Council gave a banquet at the Hotel de Ville on Monday night, in honour of Mr. Edison, M. Chautemps, president, occupied the chair. Speeches were delivered by Mr. Sommerville Tuck, M. Alphand, M. Chautemps, and others. The guests afterwards made an inspection of the machinery in the basement, which supplies the Town Hall with the electric light. He was also entertained on Tuesday by the Society of Civil Engineers. Mr. Edison left Paris on Wednesday morning for Germany.

Telephonic Communication between Dundee, Edinburgh, and Glasgow.—The National Telephone Company have begun the erection of a trunk wire between Dundee and Glasgow. It has been arranged that the wire from Dundee—a metallic loop—will be run direct to Stirling. There will be a special metallic loop wire from Stirling to Glasgow, and another from Stirling to Edinburgh, which will be joined to the Dundee-Stirling wire as required, so that the new extension which has been begun will open up telephonic communication from Dundee, not only with Glasgow, but also with Edinburgh.

The Copper Market.—Visible stocks which reached their maximum, 124,876 tons in March last, have steadily decreased, and on August 31st amounted to 105,985 tons only; these last figures comparing with 86,701 tons on August 31st, 1888, and 51,206 tons a year earlier. The more conspicuous fact, however, is the price quoted for Chili bars—namely, £43. 10s., against £40. 2s. 6d. in August, 1887, when stocks were, as shown, less by more than one-half. Deliveries for the month reached 13,923 tons—the highest total during the three years—and exceeded the supply by 2,131 tons.

The Dutch Telegraph System.—According to trustworthy information, says *Industries*, the Dutch postal authorities will shortly introduce in the Netherlands the system of "slow" telegrams. Dutch inland messages will then be transmitted under three classes, as directed by the senders. There will be "urgent" telegrams, forwarded immediately in preference to ordinary telegrams, and at a special rate; "ordinary" telegrams, dispatched in the usual way, at the usual rate; and, finally, "slow" telegrams, which will cost very much less than ordinary telegrams, but which also will take a much longer time in reaching their destination.

University College, Liverpool.—The prospectus of this College for the 1889-90 session gives full details respecting the courses, classes, fees, scholarships, and other matters likely to be of use to intending students. We notice that there is a special curriculum for students preparing for a business life, the certificates granted at the close of the course to those who pass satisfactory examinations being held in high esteem by the mercantile firms of Liverpool. Amongst the numerous series of evening lectures will be one by Dr. Oliver Lodge, who will discourse during the autumn term on "The Functions of the Ether, or Recent Progress in Electricity."

Charterhouse Science and Art Schools and Literary Institute.—The winter session of this school will commence on Saturday, September 28th, under the presidency of the Rev. H. Swann, M.A. During the late session upwards of 1,200 students, mostly elementary teachers, availed themselves of the privileges afforded by this institution, and of this number about 750 presented themselves for examination, and were successful in obtaining a large number of first-class certificates, and also an unusually large number of honours certificates, awarded by the Science and Art Department of South Kensington. Instruction of a practical character is given in most of the sciences at a very moderate fee.

The Falmouth Gas Company and the Electric Light.—At the general meeting of the shareholders of this company held on Friday last, the chairman, in moving the adoption of the report, said that now electric lighting was making such strides throughout the country they thought the time had come when an Act should be obtained. They did not know exactly what would be required, but they were desirous of getting a Gas and Electric Lighting Act, and unless notice was given before November that they intended to apply for it they should be debarred from getting it before 1891. They asked the shareholders to give them the power to give notice for an Act of Parliament if it should be deemed necessary.

The Renard Primary Battery.—It is interesting to noet that the arc and incandescent lamps lighting the rooms of the Société d'Encouragement, on the occasion of the joint meeting of the Institution of Electrical Engineers and of the Société Internationale des Électriciens, were supplied with current from the chromic chloride batteries of Commandant Renard, which he has used in connection with his dirigeable balloon. A 300 candle-power arc lamp run off 36 cells was placed in the vestibule, and a 900 candle-power arc lamp run off 42 cells lighted the refreshment room, while 16 30 candle-power incandescents were used in the various rooms. Commandant Renard estimates the cost of the candle-hour when using his battery at one-fifth of a penny.

Exports of Telegraphic Apparatus.—The Board of Trade returns for August show that our exports of telegraphic wire, &c., last month were again very much below the corresponding exports in August, 1888, and August, 1887. Owing, however, to the very large shipments early in the year the value of the aggregate shipments to date, say 31st August last, is still much above the amount at the corresponding date of the two previous years. The following is a comparative statement of exports for the three years:—

	1887.	1888.	1889.
January 1 to June 30	£188,812	£244,213	£576,456
July	195,950	21,571	32,909
August	114,162	110,323	46,452
Eight months	£498,924	£376,107	£655,817

Electric Light in the House of Commons.—The London correspondent of the *Manchester Evening Mail* says:—"An opportunity will soon be afforded to contractors to light the Houses of Parliament by electricity. Up to the present time the authorities of the building themselves have had control of the small electric installation which exists, and has been completely successful in the hands of Mr. Prim, the resident engineer; but the Treasury seems to be unwilling to sanction the large expenditure necessary to light the whole of the palace. They therefore propose to call in the aid of some outside company, which will supply electricity at a fixed price per Board of Trade unit. No definite arrangements have as yet been made in this respect, and there is not likely, as far as can be seen at present, to be much competition for the contract."

The Terrors of the Telephone.—Attention is being called on the Continent to the effects produced by a continual use of the telephone. Thus, Dr. Gellé says in one case, that of a man of great intelligence, occupying a position which obliged him to listen sometimes almost incessantly to telephonic communications, the result was a state of nervous excitement, and hyperæsthesia of the hearing and of the ear itself, to such a degree that the sounds caused vertigo and ringing in the ears, and led to the persistence of alarming vertiginous sensations. Complete rest was sufficient to remove these troubles. In another case a young *employée* in a large establishment who had to attend to telephonic messages felt her ear becoming rapidly weak, and it was soon the seat of noises and of a remarkable hyperæsthesia, and at the same time the hearing became painful.

Lomond's Pith Ball Telegraph in 1787.—The following curious reference to one of the many experimenters in pith-ball telegraphy is to be found in "Young's Travels in France," but does not seem to be generally known :—

"Oct. 16th, 1787.—In the evening to M. Lomond, a very ingenious and inventive mechanic. . . . In electricity he has made a remarkable discovery. You write two or three words on a paper, he takes it with him into a room, and turns a machine inclosed in a cylindrical case, at the top of which is an electrometer, a small fine pith ball; a wire connects with a similar cylinder and electrometer in a distant apartment, and his wife, by remarking the corresponding motions of the ball, writes down the words they indicate, from which it appears he has formed an alphabet of motions. As the length of the wire makes no difference in the effect, a correspondence might be carried on at any distance, within and without a beseiged town for instance. . . . Whatever the use may be, the invention is beautiful."

Hastings.—At the last meeting of the Town Council, the Lighting Committee recommended that application should be made by the Council for a Provisional Order authorising the supply of electricity for the following public purposes, viz.:—the lighting of streets or places and buildings belonging to or subject to the control of the Council in the borough, the exact area of supply to be determined on by the Committee. Mr. Jenner, in moving the adoption of the report, said that the Council was taking this course out of no spirit of opposition to the present Electric Lighting Company. The state of the case was simply that the Council would have with the dust destructor boiler power sufficient to work the machinery to produce their own electric light for public lighting, and the Surveyor had estimated that the saving which they would thus effect would be something like £180 a year upon the £450 now being paid for the lamps along the Front. They had no intention of supplying for private purposes, their object was simply to light the street lamps and anything else in connection with the Corporation. The motion was then carried.

Hampton Wick.—At the last meeting of the Hampton Wick Local Board the electric lighting question was considered, and it was announced that at the recent joint meeting of the Local Boards a resolution was drawn up which the representatives of each authority present agreed to accept. The heads of the agreement for obtaining the Provisional Order were :—1. That a Provisional Order should be obtained by the combined districts. 2. That the necessary capital for establishing the works should be provided according to the rateable value of each district. 3. That each of the local authorities forming the combination should be represented on the committee. 4. That each authority shall be entitled to representation on the basis of the rateable value. 5. That the committee so constituted shall have, and exercise, within the combined districts all the powers which an individual authority might exercise, each authority to bear its proportion of the expense. The resolution was "That this meeting will submit to the respective authorities in the district—the borough of Kingston, the Surbiton Improvement Commissioners, and the Local Boards of New Malden and Hampton Wick—that they shall combine for the purpose of making application for a Provisional Order to supply the districts with electricity, on the understanding that no district is to take a supply till it sees fit, and that the expense of obtaining such Provisional Order be defrayed by the combined districts in proportion to their rateable values." It was decided to discuss the matter at the next meeting of the Board.

Barnsley.—At the meeting of the Town Council on Tuesday, the Town Clerk reported that notices had been received by the Lighting Committee from three companies, the Municipal Electric Light and Power Corporation, the Yorkshire House-to-House Electricity Company, and the National Electric Supply Company, of intended applications for power to supply electricity in the borough. Since then he had had a letter from the National Electric Supply Company, stating that they should like to discuss the matter to learn whether the committee would co-operate in the lighting of an area in the district. Subsequently in another communication the company said that notices had been served in about 20 towns, but only five would be proceeded with this year. Negotiations with Leeds, Hull, and Bolton had already made considerable advance. They concluded by asking whether the Council would seek powers for themselves to supply electricity; if not, they asked permission to make a trial in the borough. Alderman Brady said he believed they ought to offer every reasonable facility to those who were able to supply the electric light. The question of public lamps was quite different. He was strongly of opinion that the Council should not apply for powers themselves, but they ought not to place an impediment in the way of public improvement coming to the town, which had already been too long delayed. He moved, "That the Town Clerk be directed to communicate with the National Electrical Supply Company, and inform them that the Council will offer no opposition to their taking steps for supplying electric light within the boundaries of the borough, subject to such arrangements as the Lighting Committee may suggest to the Council." Eventually the matter was referred to the Lighting Committee, who were empowered to take such steps as they thought proper and submit a report to next meeting.

Improvements in Railway Signalling.—Mr. Henry J. Peddie, of Edinburgh, has designed a method of railway signalling which is independent of fog or darkness. The apparatus is proposed to be used as an addition to the present means of signalling, and not as a substitute. There are two different appliances—the detector sound signal and locomotive safety steam cut-off and the railway train electric controller. The sound signal and steam cut-off consist of two parts, one attached to the sleepers and the other to the locomotive. The object is to stop a train should the engine driver not notice that the semaphore signal is at danger. Opposite the semaphore signal post a cast-iron shoe is fixed on a sleeper close to the rail. This shoe has two arms pivoted on it, and these are connected to each other and to a balance weight. They are also connected by a wire with the ordinary semaphore. When the latter indicates that the line is clear, the two arms are drawn down so that the apparatus on the locomotive passes clear of them. When the semaphore indicates danger the balance weight throws the arms up into a vertical position, in which they will catch and set in motion an apparatus fixed under the floor of the locomotive. This appliance, again, is so constructed that automatically it shuts off the steam in the engine, sounds the whistle, and applies the air brake to the whole train. Modifications of the arrangement admit of the whistle being sounded without the shutting off of the steam, and further, of its application to trains which are not supplied with the continuous brake. The other apparatus, which may be used instead, has the advantage of indicating to the signalmen in their boxes the point a train has at any time reached, and gives them control of the train during its entire journey. This electric controller involves two sets of apparatus. A battery or other source of electrical supply is placed in the signal-box. From it a conductor is led along the line to the signal post, or to the next station, or to any desired length. The conductor is a thin metal rail laid on wood between the usual rails, while one of the ordinary rails will serve as a return circuit. From the same battery wires are led to short conductors placed parallel with each other, but insulated, between the rails, at any desired distance apart. The plates of these conductors form the open poles of the electric circuit. A pendant wheel from the locomotive tender is so placed that it touches the conductors as the engine passes along. In so doing the wheel completes the circuit, an electric bell in the signal box is rung, and an indicator shows the point the train has reached. To the locomotive itself another pendant wheel is attached. It travels along the long conductor, and from the pendant wheel a wire is carried to an electro-magnet placed below an air or steam cylinder. In the event of a train passing a signal at danger an intimation of the fact is conveyed to the signalman in the box, who will set a danger signal. The effect of this will be to set in motion apparatus which will shut off the steam in the advancing engine, sound the whistle, and apply the brake to the whole train. In short, the signalman has at all times complete control over a train. Various modifications and simplifications are suggested by the patentee for different cases, and a similar apparatus is applicable to mines.

THE PARIS EXHIBITION.

Prof. Elihu Thomson's Personal Exhibit.

This interesting exhibit is in the United States Section of the Industrial Courts. It consists partly of machines and instruments of a practical character, and partly of apparatus for illustrating alternate-current phenomena, some of the latter being those employed by Prof. Thomson in his recent researches which were described in *The Electrician*, Vol. XIX., p. 104.

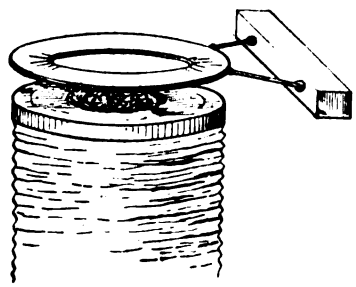

Fig. 1.

Among the latter description of apparatus is a coil, shown in Figs. 1 to 3; it stands about a foot high, has a core made up of pieces of iron wire, and is wound to carry a current up to

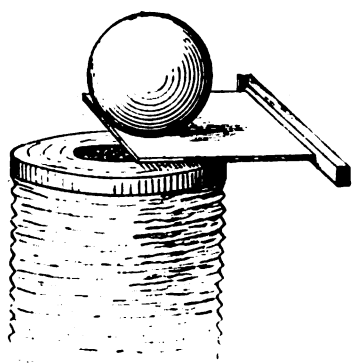

Fig. 2.

40 amperes. Power is supplied from the Thomson-Houston stand in the Palais des Machines for showing the experiments with this coil, and also for working the machine and instruments in the exhibit.

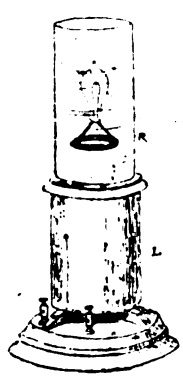

Fig. 3.

Amongst other remarkable experiments* which may be made with the coil alone, we may describe the following:—If a light metal ring is held over the coil while an alternating current is passing round it, the ring is thrown up into the air when released. When a ring attached to a holder to prevent lateral motion is placed on the top of the coil (Fig. 1) the force of repulsion will keep it suspended in the air about the coil. A hollow copper ball, if placed on the top of the coil, immediately runs off, but if partially shielded by a metal plate on the edge of which it is placed (Fig. 2), it begins to spin round; the direction of motion varies with its position, the unshielded part tending to turn towards the core.

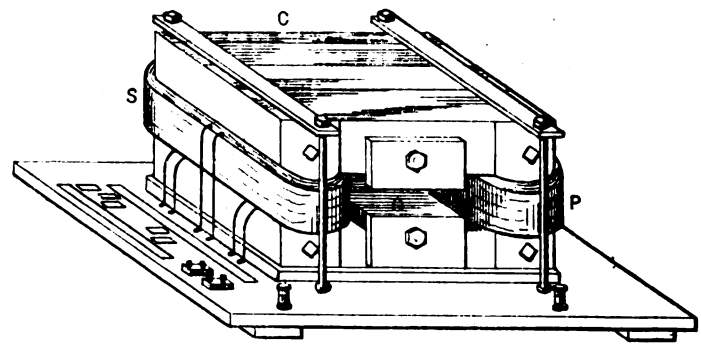

Fig. 4.—Elihu Thomson's Constant-Current Transformer.

Another experiment is illustrated in Fig. 3. Here an incandescent lamp is joined up in circuit with a ring-shaped coil of insulated wire, R, and placed in a vessel of water over the large coil, L, carrying the alternating current. The lamp is illuminated by the currents induced in the ring, and at the same time the repulsion causes both to rise in the water. The light

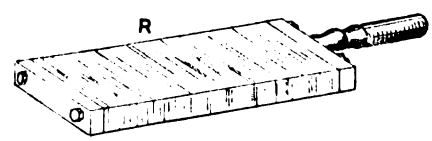

Fig. 4*a*.—Regulator used in connection with the Constant-Current Transformer.

given by the lamp naturally depends to some extent upon the depth at which it is floating. If the copper ball is placed in the water it is also repelled upwards, and made to rotate at the same time.

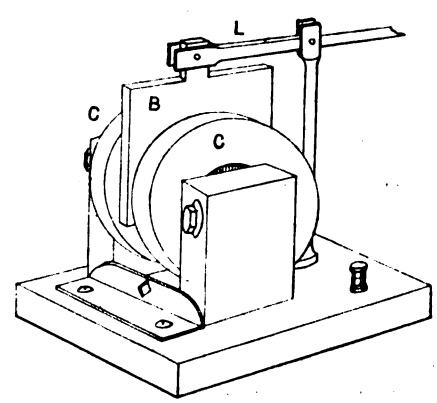

Fig. 5.

Among the practical appliances is a constant-current transformer, shown at Fig. 4. This is made up of a laminated iron core, C, having the primary coil P wound upon one side of the arc, and the secondary S on the other. The magnetic circuit is, however, almost short-circuited in the centre G, where the opposite sides of the core approach each other very closely. The gap can, however, be still further diminished by inserting the regulator R (Fig. 4*a*), which consists of a number of small

* All or nearly all these experiments are based upon the possibility of producing a powerful repulsive effect betwixt two circuits, one of which is traversed by an alternating, whilst the other circuit, which is usually of low resistance, is subject to the inductive influence of the first. The reason for the observed repulsion was first clearly explained by Dr. J. Fleming (in *The Electrician*, of May 6, 1887), who also independently discovered the effect at or about the time of its discovery by Prof. E. Thomson.

Digitized by Google

plates attached to a handle. The total number of lines passing through the secondary can thus be diminished to any required extent by inserting R to a suitable distance within the gap G, and in this way a certain crude regulation is obtainable. The device is obviously of little practical value.

The "reactive" coil illustrated in connection with the description of the Thomson Electric Welding Company's exhibit (*The Electrician*, August 30) is also shown at this stand.

Another repulsion effect is shown in the piece of apparatus illustrated in Fig. 5; it has received a practical application as the regulator of an arc lamp. The current passes round the coils C C, and on reaching a certain strength causes the plate B, attached to the lever L, to rise from its position between the coils. When inserted into an arc lamp the mechanism is arranged as follows. The wheels and pinions which gear into the rack rods carrying the carbon holders are fixed into a light frame suspended by links, like a Watts parallel motion, the rod

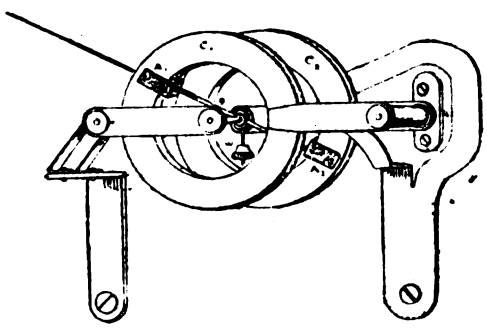

Fig. 6.—Elihu Thomson Ammeter.

L being one of them. When the current in the coils C C, which are connected up as a shunt to the carbons, becomes strong, the brass plate is repelled upwards causing the other end of L to fall, and with it the frame above mentioned, thereby liberating one of the wheels from a catch rigidly fixed about it, and allowing the carbon rods to run down.

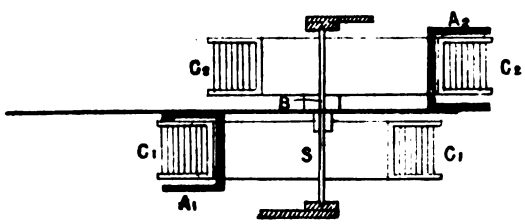

Fig 7.—Elihu Thomson Ammeter (Plan).

Among the instruments designed and invented by Prof. Thomson are one or two forms of the meter that was described in *The Electrician* of May 24, 1889, p 60. At the Thomson-Houston stand one of these may be seen working regularly on one of the incandescent lamp circuits.

A new form of ammeter and voltmeter is shown in Figs. 6 and 7. Two coils, C_1 C_2, are fixed in a vertical position as shown, and wound with copper tape or fine wire, according to the purpose for which they are to be used. Two soft iron shoe-shaped armatures, A_1 and A_2, are fastened at either end of a light arm, B, attached to a spindle, S, which is free to turn in light bearings. The coils and spindle are set with their axes parallel, but not in the same straight line, as will be noticed from the plan, Fig. 7. In other words, the spindle is pivotted excentrically to either coil. When a current flows round the coils the armatures tend to move round, the amount being indicated by the pointer, which is a continuation of the arm B. It is a gravity instrument, the movement being controlled by the adjustable weight W. For very large currents one coil only is used, having only one turn, the action being the same as with the two coils. It is obvious that the instruments may be used either for continuous or for alternating currents.

Besides the above, there is a voltmeter constructed on the electrostatic principle. Its working parts consist of two pairs of cheeks, fixed one behind the other, the front pair being attached to the frame of the instrument, and the back pair suspended on light bearings, with a pointer attached to them. The two pairs of cheeks are insulated from one another, and one pair is attracted towards the other according to the difference of potential between them. The instrument closely resembles the electrostatic voltmeter designed by Sir William Thomson.

Two alternate-current motors are also exhibited. Both work more or less on the same principle, viz., that of the repulsion between an electro-magnet carrying an alternating current and another coil that is short-circuited, as illustrated by all the ex-

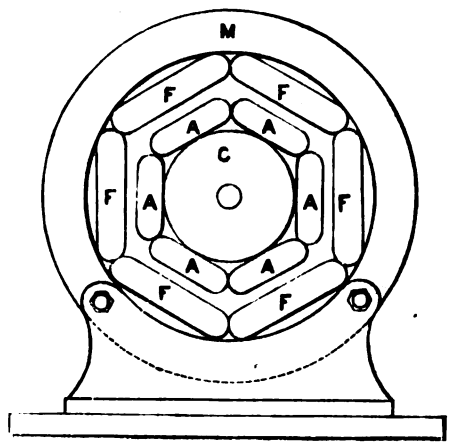

Fig. 8.—Elihu Thomson Alternate-Current Motor.

periments previously mentioned. The general construction of one of these motors will be gathered from the sketch, Figs. 8 and 8*a*. Six coils, F, are fixed inside a laminated frame, M, and form the field magnets. The armature consists of a core, C, with six similar coils, A, attached to it; the form of these coils is shown in Fig. 8*a*. The current passes through the field-magnet coils F, which are wound in opposite directions, then by way of a commutator through the armature coils. This commutator, however, only comes into action when the machine is started, the brushes being short-circuited as soon as the motor has attained its proper speed;

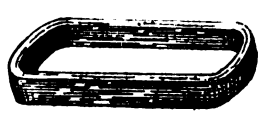

Fig. 8*a*.—Armature Coil of the Elihu Thomson Alternate-Current Motor.

it is fixed at the end of a hollow spindle, like those of the Thomson alternating dynamo, but has an arrangement inside by which two contacts fly out (by centrifugal force) and short-circuit the armature coils when the motor increases its speed. The stops against which the brushes come when they are short-circuited also have the effect of lifting them from the commutator. By means of this device the machine is made self-starting. The other motor was described and illustrated in *The Electrician* for August 2, p. 321.

The Edinburgh Exhibition.—At the last meeting of the Executive Council the catalogue was agreed upon. It is divided into three divisions. Division I.: Electrical Engineering and inventions, contains six sections, namely:—Section I.: Production of electricity; II.: Electrical conductors; III.: Measurements; IV.: Application of electricity; V.: Bibliographic collection of works relating to electricity, plans, drawings, &c.; VI.: Historical collection. The other two divisions are:—II.: General inventions and industries, and includes sixteen sections; III.: Fine arts.

PARIS INTERNATIONAL ELECTRICAL CONGRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

Saturday, August 31.

This evening the French members of the Congress entertained their foreign colleagues at a banquet at the Hotel Continentale. The gathering was large and brilliant, about 350 covers being laid. M. Mascart presided, with Sir William Thomson on his right hand, Mr. Preece on his left, and M.M. Cochery and Berger next them. The "*carte du menu*" was elaborately designed with symbolic electrical representation referring to Volta, Faraday, Ruhmkorff, Ampère, Oersted, Gauss, Ohm, Galvani, Gramme, Jamin, Foucault, Daniell, Bunsen, Joule, Siemens, Graham Bell, Edison, Becquerel, and Wollaston. The French have too much respect for "*la cuisine*" to tolerate any joking with respect to the eatables, and there appeared on the *menu* no "*potages électriques*," "*côtelettes Jablochkoff*," or "*salade Edison*." M. MASCART proposed the health of M. Cochery, ex-Minister of "*Postes et Telegraphes*" in a humorous speech, in which he said M. Cochery has been made an electrician by force ("*electricièn par nécessité*"), much to the advantage of his countrymen and of science, and hinted that the success of the Congress was due to M. Cochery's genius in securing "unanimity." This was a side-poke at M. Cochery's reputation for securing votes at meetings "*nem. contradicente*" by the simple device of leaving no time for anyone to speak before asking for a show of hands.

In replying, M. COCHERY expressed his earnest hope that the International Society of Electricians would be universally supported by the adherence of scientists in all countries. M. BERGER spoke next, and said it was the desire of the organisers of the Exposition to offer a world-wide hospitality, and in their name he offered a welcome to the guests of the evening, not only on behalf of French science, but also on behalf of France herself.

In replying to this speech on behalf of the foreign guests, Sir WILLIAM THOMSON, who was greeted with hearty and repeated cheers, said that during the past week the meetings of the Congress had been to him a source both of pleasure and of profit. In the name of his own countrymen and of all the other foreigners present, he tendered to the President and to his colleagues heart-felt thanks for the hospitality and the kindness that had been shown them in every direction. For his own part, a feeling of profound gratitude had been implanted in his mind which would never be effaced from his memory. Paris had always appeared to him the natural centre for cosmopolitan gatherings of this sort—it was the capital of science, the place where all could meet on common ground and show each other international friendship. There was something about Paris that made these Congresses that had been held here peculiarly pleasant. For them, and for the strangers from all parts of the world who had joined with them, it seemed to be the home of concord and "*unanimity*," and the "happy land." This Congress had not been less agreeable or less successful than its predecessor in 1881. Not only for science itself and for the interests of the workshop, but also for results beneficial to the world at large, the work of this Congress would be gratefully remembered. He hoped it would not be the last time we should meet here. Among all countries France takes the first place for hospitality to people from every part of the world, and for skill in the organisation of such affairs as those with which we have been occupied during the past week, and he hoped she would long continue to hold the position she had so gracefully assumed as the rendezvous of the Congress of the world.

As he sat down, the enthusiastic cheers with which Sir William had been received were again and again repeated.

M. TOURITINIER, of Geneva, was the next speaker, and then M. STOLETOW proposed the health of M. Mascart, a toast that was very cordially received.

M. ABDANK-ABAKANOWICZ then spoke in eulogy of those who had conceived the idea of the Congress of 1881, and had carried it out so much to the benefit of science. In the name of the Electrical Engineers of America he cordially invited the electricians of the Old World to the projected Congress in connection with the New York Exhibition of 1892.

The company then adjourned to another and cooler hall for the purpose of discussing the events of the week in an informal fashion over their coffee and cigars.

Thus has ended a Congress which has certainly been a very pleasant *réunion*, and which in some respects will be remembered as as important one. Its importance cannot for a moment be compared to that of 1881. There have been several influences tending to lower the effect it might otherwise have had. The first of these is that congresses this year are at a discount. There has been such a deluge of congresses in connection with this Paris Exhibition—congresses of all sorts: of millers, greengrocers, and firemen, as well as of politicians, literary men, and scientists—that the public has lost count of them, and cannot pay any attention to them. During this week the congress of "*pompiers*" (firemen) attracted much more public attention in Paris than did the Electrical Congress, it being accompanied by grand displays on the boulevards. Among the general public our Congress has stimulated as little thought as if it had not been held, and it would be the most foolish and priggish affectation to imagine that the influence and authority of the Congress has not thereby been greatly diminished.

In the second place, Germany has been practically unrepresented, and, in spite of Sir W. Thomson's presence, it must be frankly confessed that there was so small a number of English electricians present that they could not be taken as authentically, or, at any rate, in any complete way, representing the intelligence of our own country. The American representation was also notably weak. Again, it can hardly be said that the business of the Congress was at all sufficiently or well prepared, or that it was well regulated in the course of the proceedings. Much time was taken up in discussions, whose proper place should have been the different local or national societies. The really great questions of world-wide interest and importance were allowed to be thrust aside to a great extent by these comparatively unimportant proceedings, and were in some cases simply left alone, and in others decided upon after absurdly short and insufficient deliberation.

Fortunately, most of the leading decisions of the Congress merely formally ratify what has already been long established by general agreement. The case would have indeed been bad for the authority and influence of the Congress if it had stultified itself by presuming to decree a three-minutes' limit for telephonic conversations. If it had done that, it would have very soon become apparent what little reality such a pretension to international authority it possessed. As regards the adoption of the name "quadrant" for unit coefficient of self-induction, it was unfortunate that there was no one there to defend the term "secohm." Whatever objection may be taken to this latter, it has, at any rate, an evident electrical meaning, whereas "quadrant" is absolutely unmeaning in the connection in which the Congress has placed it. It is *not* the quadrant of the earth's surface, and if it were, that fact could have no logical influence in the solution of the problem of the choice of the best terms by which to describe the phenomena of self-induction. Nevertheless, we desire frankly and fully to acknowledge the utility and importance of this meeting; to express also the hope that its decisions will meet with general support, and, finally, to record our grateful appreciation of the great kindness and hospitality of our French hosts.

CONTRIBUTIONS TO THE CHEMISTRY OF STORAGE BATTERIES.*

BY E. FRANKLAND, D.C.L., F.R.S.

Under this title I communicated to the Royal Society, in February, 1883,† the results of some experiments on the reactions occurring during the charging and discharging of a storage cell. I showed that no appreciable part of the storage effect was due to occluded gases, as had been previously suggested by some chemists and physicists; but that the act of charging consisted essentially in the decomposition of lead sulphate, whilst the discharge was produced by the recomposition of this salt.

* A Paper read before the Royal Society, June 20, 1889.

† *Proceedings* of the Royal Society, Vol. XXXV., p. 67.

Digitized by Google

The establishment of these, as practically the only reactions going on in a storage cell, enabled me to prescribe a very simple method by which the charge in any cell could be ascertained, for as sulphuric acid is liberated during the charging and absorbed by the active material of the plates during discharge, the amount of charge could at any time be measured by ascertaining the amount of free sulphuric acid in the cell; in other words, by simply determining the specific gravity of the electrolyte; and this method has since been very generally adopted by the users of storage batteries.

In continuing these experiments it soon became evident that the lead sulphate formed and decomposed in the cell could not be the ordinary white sulphate hitherto known to chemists, because, in the first place, the active material of the plates always remains coloured, even after discharge; and, secondly, because whenever white sulphate is produced through abnormal reactions in the cell, it is afterwards decomposed only with extreme difficulty by the electric current.

In order to obtain some light upon the composition of the sulphate formed and decomposed in the cell, I have studied the action of dilute sulphuric acid upon litharge and minium.

Action of Dilute Sulphuric Acid on Litharge.

Finely-powdered litharge was treated with successive portions of dilute sulphuric acid until the liquid remains strongly acid after prolonged trituration. The resulting insoluble buff-coloured powder was washed with water till free from acid, and dried first at 100°C. and afterwards at 150—160°. The loss at this higher temperature was less than 0·2 per cent., and was therefore due to hygroscopic moisture.

PbO and SO_3 were then determined in the dried compound as follows:—The salt was dissolved in a small quantity of pure concentrated solution of caustic potash, and the solution, after dilution, was saturated with CO_2. (According to H. Rose, COPbo″ is soluble in $COKo_2$, but not in COHoKo.) Any excess of CO_2, which might have caused the COPbo″ to dissolve, was avoided by warming the liquid with the precipitate on the water-bath to a temperature at which the COHoKo begins to dissociate. The liquid was then allowed to cool and stand twelve hours before filtering. The COPbo″ was filtered off, converted into nitrate, and precipitated and weighed as sulphate. The sulphuric acid was determined in the filtrate from the COPbo″.

1·2964grms. of the salt gave 0·6647grm. baric sulphate and 1·4437grms. plumbic sulphate.

These numbers agree closely with the formula—

$$(^{c}_{3}(SO\,(PbO)_5,$$

as is seen from the following comparison of calculated and experimental numbers:—

	Calculated.		Found.
$3SO_3$	240	17·71	17·61
$5PbO$	1115	82·29	81·96
	1355	100·00	99·57

These analytical results suggest the following graphic formula:—

$$\begin{array}{ccccc} PbO_2 & & PbO_2 & & \\ \| & & \| & & \\ S=O_2= & S & =O_2= & S & \\ \| & & \| & & \| \\ PbO_2 & & PbO_2 & & PbO_2 \end{array}$$

The formation of this salt may be represented by the following equation:—

$$\underset{\text{Litharge.}}{5\,PbO} + \underset{\text{Sulphuric acid.}}{3\,SO_4H_2} = \underset{\text{Buff lead salt.}}{S_3Pb_5O_{14}} + \underset{\text{Water.}}{3OH_2}.$$

Action of Dilute Sulphuric Acid on Minium.

Minium was treated with dilute sulphuric acid in exactly the same way as litharge, and the resulting brownish-red compound dried first at 100° C. and afterwards at 150—160°. The loss at this higher temperature was again less than 0·2 per cent.

PbO, SO_3, and excess of oxygen were then determined in this salt in the following manner:—The salt was first treated with concentrated hydrochloric acid in order to reduce all the lead to the non-oxide stage. The resulting mixture was then dissolved in caustic potash and treated as already described. The excess of oxygen was determined by finding the loss of weight which resulted from the evolution of CO_2 when the salt was treated with oxalic acid and dilute nitric acid.

2·1136grms. of the salt gave 1·1978grms. baric sulphate and 2·2710grms. lead sulphate.

1·5110grms. treated with oxalic acid and dilute nitric acid evolved 0·0910grm. CO_2.

These numbers correspond to the following percentages:—

SO_3	19·45
PbO	79·03
O	1·09
	99·57

which agree with the formula—

$$S_2Pb_3O_{10},$$

as is seen from the following comparison:—

	Calculated.		Found.
S_2	64	7·57	7·78
Pb_3	621	73·49	73·36
O_{10}	160	18·94	18·43
	845	100·000	99·57

The composition of this salt may be represented graphically, thus:—

$$\begin{array}{ccccc} & & O & & \\ & & \| & & \\ Pb & =O_2=S= & O_2= & Pb & \\ & =O_2=S= & O_2= & Pb & \\ & & \| & & \\ & & O & & \end{array}$$

The formation of this salt is expressed by the following equation:—

$$\underset{\text{Minium.}}{Pb_3O_4} + \underset{\text{Sulphuric acid.}}{2SO_4\,H_2} = \underset{\text{Red lead salt.}}{S_2Pb_3O_{10}} + \underset{\text{Water.}}{2OH_2}.$$

These, then, are the salts which constitute the original active material of storage cells when that material is formed by the admixture of sulphuric acid with litharge or minium respectively, and it is highly probable that one or the other of these salts takes part in the electrolytic processes of the storage battery. It is fortunate that these hitherto unknown salts (and not the ordinary known sulphate) are formed in the cell reactions; for, in the alternative case, lead storage batteries would be practically valueless.

If the buff lead salt be the active material of the battery plates, then the following equations express the electrolytic reactions taking place in the cell:—

I. In charging—

(*a*). *Positive Plates.*

$$\underset{\text{Buff lead salt.}}{S_3Pb_5O_{14}} + \underset{\text{Water.}}{3OH_2} + O_5 = \underset{\text{Lead peroxide.*}}{5PbO_2} + \underset{\text{Sulphuric acid.}}{3SO_4H_2}.$$

(*b*). *Negative Plates.*

$$S_3Pb_5O_{14} + 5H_2 = 5Pb + 3SO_4H_2 + 2OH_2.$$

II. In discharging—

(*a*). *Positive Plates.*

$$5PbO_2 + 3SO_4H_2 + 5H_2 = S_3Pb_5O_{14} + 8OH_2.$$

(*b*). *Negative Plates.*

$$5Pb + 3SO_4H_2 + O_5 = S_3Pb_5O_{14} + 3OH_2.$$

If the red lead salt be the active material, then the following equations express the same electrolytic reactions:—

I. In charging—

(*a*). *Positive Plates.*

$$\underset{\text{Red lead salt.}}{S_2Pb_3O_{10}} + O_2 + 2OH_2 = \underset{\text{Lead peroxide.}}{3PbO_2} + \underset{\text{Sulphuric acid.}}{2SO_4H_2}.$$

(*b*). *Negative Plates.*

$$S_2Pb_3O_{10} + 4H_2O = 3Pb + 2SO_4H_2 + 2OH_2.$$

II. In discharging—

(*a*). *Positive Plates.*

$$3PbO_2 + 2SO_4H_2 + 2H_2 = S_2Pb_3O_{10} + 4OH_2.$$

(*b*). *Negative Plates.*

$$3Pb + 2SO_4H_2 + 2O_2 = S_2Pb_3O_{10} + 2OH_2.$$

An inspection of these equations discloses, in the case of the red lead salt, a fact which has already been roughly observed in practice, viz., that only half as much active material is electrolytically decomposed on the negative as on the positive plates; whence it follows that the weight of active material on the negative plates need not exceed one-half of that upon the positive plates; for, in the decomposition of the electrolyte, equivalent quantities of oxygen and hydrogen are evolved—that is to say, two atoms of hydrogen for each atom of oxygen. But in the decomposition of the red lead salt four times as many atoms of hydrogen are required to reduce the salt to metallic lead as atoms of oxygen which are necessary to transform the lead of the salt into peroxide. When, however, the active material of the positive plate has once been converted into peroxide of lead, it seems probable that the red salt only is formed; at all events, until the discharge at high potential is nearly completed, when there are indications of the production of the buff-coloured salt. But this is a point requiring further investigation.

I have to thank Dr. F. R. Japp, F.R.S., for his assistance in the analytical work of this investigation.

* Mr. Fitzgerald considers that this peroxide is hydrated.

THE POSTMASTER-GENERAL'S REPORT.

Whatever may be thought of the financial position of the Telegraph Service, there is but one opinion as to its efficiency and its extraordinary development since it came into the hands of the Post Office. Not only have the charges been greatly reduced, but the facilities for the transmission of telegrams have in every way been enormously enlarged. According to the POSTMASTER-GENERAL'S Report just published for the year ended the 31st March, 1889, the number of offices at which telegraph business can now be transacted in the United Kingdom exceeds seven thousand, and they are being constantly increased. Looking at the figures representing the extent to which the public have taken advantage of these privileges during the nineteen years the telegraphs have been under Post Office management, we find that the amount of inland telegraphic business is nearly six times what it was at the beginning of that period. Commencing with less than ten million messages per annum, the numbers have gradually risen to little short of fifty-eight million, generally by progressive leaps of from one and a-half to three millions each year. In the year 1886-87, when the tariff, which was reduced from 1s. to 6d. in the October previous, had been in operation during the whole twelve months, there was a remarkable bound from thirty-nine millions to fifty millions; but in the two years succeeding, the increase has been at the rate of about three and a-quarter and four and a-quarter millions respectively. This is approximately the rate at which the number of telegrams increased during the first few years of the shilling tariff, between 1870 and 1873. After then the normal increase settled down to two millions, or thereabouts: and it seems not unlikely that the progressive increase which has taken place under the sixpenny tariff since the autumn of 1885 will be subject to a similar law. The

Digitized by Google

figures are worth noting carefully, as affording some indication of the financial results of that experiment.

As regards its public utility there can be no question that the sixpenny tariff has been a great success. If the present rate of increase be maintained, at the end of the current financial year the number of telegrams will have nearly doubled since 1885, a fact which thoroughly justifies the sanguine expectation of those who were responsible for introducing the last great reform of telegraph charges on the grounds of public convenience. Of the financial situation, however, as the POSTMASTER-GENERAL reminds us, we cannot speak with the same confidence. For one thing, the public appear to have mastered the lesson of brevity, which the department set them to learn in 1885, perhaps a little too cleverly. It was thought that although the addresses would be materially curtailed the message as a whole would not be very greatly reduced. But the public have taken the sixpenny tariff literally, and are rapidly acquiring the habit of getting their money's worth within the compass of the initial rate. Year by year the average price paid for each telegram is being gradually reduced; and as every separate transaction costs the department a definite sum irrespective of the size of the message, it is easy to see that an increase in the amount of business done, represented by an increased number of messages, will not, at this rate, bring a proportionately increasing sum to the revenue. Again, the senders of Press messages, by availing themselves more largely of the privilege of sending copies of the same telegram to several newspapers, are occupying the wires more than ever without adding anything to telegraph receipts; and as this class of business is said to be unremunerative at the best, its increase cannot be regarded as satisfactory from a financial point of view. Mr. RAIKES very properly again draws attention to the continued growth of free messages sent by the Railway Companies under an agreement with them when the telegraphs were acquired by the Post Office. These messages, numbering over a million per annum, are a dead loss, and until the bargain is cancelled or commuted, must continue to be so. Taking all these considerations into account, and the fact that every year's increase of business must be met by augmented staff, enlarged accommodation, and additional plant and apparatus, the net profits of the telegraph service cannot be expected to keep pace with the increase of messages.

The gross receipts for 1888-9 amounted to £2,129,669, against £1,992,949 for 1887-8; but the expenditure also has risen from £1,999,033 to £2,042,394 in the same periods; and although the deficit, taking into account the interest on capital, is less than it has been since 1882-3, it stands at the respectable sum of £239,142—a sum which at the present rate of net profits it will take several years of prosperity to wipe out. It is often complained that this annual interest, amounting to £326,417, on the original purchase-money continues to be placed to the year's account, and it is urged that if the expenditure on extensions and accommodation were treated in the same way instead of being charged to expenditure, the telegraphs would be working at a profit. The rule of public departments, however, is to charge such items to the year's account, for the very excellent reason that this is probably the only way of checking extravagant expenditure where there are no shareholders to be consulted. We think it an excellent rule, and the departure from it in the case of the large sum expended on the purchase of the telegraphs ought not to be taken as a pretext for a similar course in respect to expenditure which in ordinary commercial business would be placed to capital account. Whether it is expedient to keep on debiting the telegraph service year after year with the interest on the original outlay is another matter. But clearly the financial critics cannot have it both ways; for if the annual capital expenditure were charged to capital account, the first capital outlay also must be so treated, and in that case the whole accumulated arrears of interest would stand against the telegraph service, and this could never be paid off within measurable distance of time. Probably the requirements of the case will be met when the telegraphs are able to pay interest on the purchase-money with a small margin to the good; and this we may hope they will do at no very distant date, though not so soon as some prophets asked us to expect.

All predictions on that point, however, are rendered uncertain by the change which has this year taken place in the relations of the Post Office with the Anglo-European cable systems. On the 1st April the Submarine Telegraph Company's business was acquired jointly by the Governments of England, France, and Belgium, the German Government purchasing at the same time the cable of the German Union Company. The terms of purchase were, to say the least of it, extremely easy; the rates between England and the Continent have been reduced; the speed of working already has been greatly increased, and it is known that the traffic is rapidly growing. The arrangement is not altogether what we should have liked for this country; but considering the international jealousies involved, it was, perhaps, the best that could be made, and undoubtedly it ought to be a source of considerable revenue to the English telegraph department. Next year's report will be looked forward to with some interest in this relation. Our share in the transaction cost £67,163; and this sum, we suppose, will be placed to the current expenditure account, in compliance with the rule referred to above. Nevertheless it will surprise us if the net balance is materially diminished by that proceeding; in other words, we expect that the profits of the undertaking will in a very short time more than cover the small sum invested in taking it over. No mention is made by the POSTMASTER-GENERAL of his recent correspondence with the Telephone Companies; but the language he employs in respect to the Submarine Telegraph Company is significant of his general policy with regard to telegraphs outside the jurisdiction of the State.

ON THE PROPAGATION OF ELECTRIC WAVES THROUGH WIRES.

BY PROF. H. HERTZ.*

If a constant electric current flows in a cylindrical wire, its intensity is the same in all parts of the section of the wire. But if the current is variable, self-induction causes a deviation from this most simple distribution. For, since the inner parts of the wire are in the mean less distant from all the rest than are those on the circumference, induction opposes alterations of the current in the interior of the wire more strongly than at the circumference; and in consequence of this the flow is confined to the exterior of the wire. If the current alters its direction a few hundred times per second the deviation from the normal distribution is no longer imperceptible; this deviation increases rapidly with the rate of alternation, and when the current alternates many millions of times per second, according to theory almost the whole interior of the wire must appear free from current, and the flow must be confined to the immediate neighbourhood of the circumference. In such very extreme cases the hitherto accepted theory of the phenomenon is plainly not without physical difficulties; and preference must be given to another view of the subject, which was indeed first put forward by Messrs. Heaviside† and Poynting‡ as the true interpretation of the equa-

tions of Maxwell as applied to this case. According to this view, the electric force which determines the current is in no wise propagated in the wire itself, but under all circumstances enters the wire from without and spreads itself in the metal comparatively slowly, and according to similar laws as changes of temperature in a conductor of heat. If the forces in the neighbourhood of the wire are continually altering in direction, the effect of these forces will only enter to a small depth into the metal; the more slowly the changes take place, so much deeper will the effect penetrate; and if, finally, the changes follow one another infinitely slowly, the force has time to fill the whole interior of the wire with uniform intensity.

In whatever way we wish to regard the results of the theory, an important question is, whether it agrees with fact. Since, in the experiments which I carried out on the propagation of electric force, I made use of electric waves in wires which were of extraordinarily short period, it was convenient to prove by means of these the accuracy of the inferences drawn. In fact, the theory was proved by the experiments which will now be described; and it will be found that these few experiments suffice to confirm in the highest degree the view of Messrs. Heaviside and Poynting. Analogous experiments, with similar results, but with quite different apparatus, have already been made by Dr. O. J. Lodge,* chiefly in the interest of the theory of lightning conductors. Up to what point the conclusions are just which were drawn by Dr. Lodge in this direction from his experiments must depend in the first place on the velocity with which the alterations of the electrical conditions really follow each other in the case of lightning.

The apparatus and methods which are here mentioned are those which I have described in full in previous memoirs.† The waves used were such as had in wires a distance of nearly 3 meters between the nodes.

1. If a primary conductor acts through space upon a secondary conductor, it cannot be doubted that the effect penetrates the latter from without. For it can be regarded as established that the effect is propagated in space from point to point, therefore it will be forced to meet first of all the outer boundary of the body before it can act upon the interior of it. But now a closed metallic envelope is shown to be quite opaque to this effect. If we place the secondary conductor in such a favourable position near the primary one that we obtain sparks 5 to 6 millimetres long, and surround it now with a closed box made of zinc plate, the smallest trace of sparking can no longer be perceived. The sparks similarly vanish if we entirely surround the primary conductor with a metallic box. It is well known that with relatively slow variations of current the integral force of induction is in no way altered by a metallic screen. This is, at the first glance, contradictory to the present experiments. However, the contradiction is only an apparent one, and is explained by considering the duration of the effects. In a similar manner a screen which conducts heat badly protects its interior completely from rapid changes of the outside temperature, less from slow changes, and not at all from a continuous rising or lowering of the temperature. The thinner the screen is the more rapid are the variations of the outside temperature, which can be felt in its interior. In our case also the electrical action must plainly penetrate into the interior, if we only diminish sufficiently the thickness of the metal. But I did not succeed in attaining the necessary thinness in a simple manner; a box covered with tinfoil protected completely, and even a box of gilt paper, if care was taken that the edges of the separate pieces of paper were in metallic contact. In this case the thickness of the conducting metal was estimated to be barely $\frac{1}{20}$ millimetre. I now fitted the protecting envelope as closely as possible round the secondary conductor. For this purpose its spark-gap was widened to about 20 millimetres, and in order to detect electrical disturbances in it an auxiliary spark-gap was added exactly opposite the one ordinarily used. The sparks in this latter were not so long as in the ordinary spark-gap, since the effect of resonance was now wanting, but they were still very brilliant. After this preparation the conductor was completely enclosed in a tubular conducting envelope as thin as possible, which did not touch it, but was as near it as possible; and in the neighbourhood of the auxiliary spark-gap (in order to be able to use it) the envelope contained a wire-gauze window. Between the poles of this envelope brilliant sparks were produced, just as previously in the secondary conductor itself; but in the enclosed conductor not the slightest electrical movement could be recognised. The result of the experiment is not affected if the envelope touches the conductor at a few points; the insulation of the two from each other is not necessary in order to make the experiment succeed, but only to give it the force of a proof. Clearly we can imagine the envelope to be drawn more closely round the conductor than is possible in the experiment; indeed, we can make it coincide with the outermost layer of the conductor. Although, then, the electrical disturbances on the surface of our conductor are so powerful that they give sparks 5 to 6 millimetres long, yet at $\frac{1}{20}$ millimetre beneath the surface there exists such perfect freedom from disturbance that it is not possible to obtain the smallest sparks. We are brought, therefore, to the conclusion that what we call an induced current in the secondary conductor is a phenomenon which is manifested in its neighbourhood but to which its interior scarcely contributes.

2. One might grant that this is the state of affairs when the electric disturbance is conveyed through a dielectric, but maintain that it is another thing if the disturbance, as one usually says, has been propagated in a conductor. Let us place near one of the end plates of our primary conductor a conducting-plate, and fasten to it a long, straight wire; we have already seen in the previous experiments how the effect of the primary oscillation can be conveyed to great distances by the help of this wire. The usual theory is that a wave travels along the wire in this case. But we shall try to show that all the alterations are confined to the space outside and the surface of the wire, and that its interior knows nothing of the wave passing over it. I arranged experiments first of all in the following manner:—A piece about 4 metres long was removed from the wire conductor and replaced by two strips of zinc plate 4 metres long and 10 centimetres broad, which were laid flat one above the other, with their ends permanently connected together. Between the strips along their middle line, and therefore almost entirely surrounded by their metal was laid along the whole 4 metres length a copper wire covered with gutta-percha. It was immaterial for the experiments whether the outer ends of this wire were in metallic connection with, or insulated from, the strips; however, the ends were mostly soldered to the zinc strips. The copper wire was cut through in the middle, and its ends were carried, twisted round each other, outside the space between the strips to a fine spark-gap, which permitted the detection of any electrical disturbance taking place in the wire. When waves of the greatest possible intensity were sent through the whole arrangement there was nevertheless not the slightest effect observable in the spark-gap. But if the copper wire was then displaced anywhere a few decimetres from its position, so that it projected just a little beyond the space between the strips, sparks immediately began to pass. The sparks were the more intense according to the length of copper wire extending beyond the edge of the zinc strips and the distance it projected. The unfavourable relation of the resistances was therefore not the cause of the previous absence of sparking, for this relation has not been changed; but the wire being in the interior of the conducting mass was at first deprived of the influence coming from without. Moreover, it is only necessary for us to surround the projecting part of the wire with a little tinfoil in metallic communication with the zinc strips, in order to immediately stop the sparking again. By this means we have brought the copper wire back again into the interior of the conductor. If we bend another wire into a fairly large arc round the projecting portion of the gutta-percha wire, the sparks will be likewise weakened; the second wire takes off from the first a certain amount of the effect due to the outer medium. Indeed, it may be said that the edge of the zinc strip itself takes away the induction from the middle of the strip in a similar manner. For if we now remove one of the strips, and leave the insulated wire simply resting on the other one, we certainly obtain sparks continuously in the wire; but they are extremely weak if the wire lies along the middle of the strip, and much stronger when near its edge. Just as in the case of distribution under electrostatic influence the electricity would prefer to collect on the sharp edge of the strip, so also here the current tends to move along the edge. Here, as there, it may be said that the outermost parts screen the interior from outside influence.

The following experiments are somewhat neater and equally convincing. I inserted into the conductor transmitting the waves a very thick copper wire, 1·5 metre long, whose ends carried two circular metallic disks of 15 centimetres diameter. The wire passed through the centres of the disks; the planes of the disks were at right angles to the wire; each of them had on its rim 24 holes, at equal distances apart. A spark-gap was inserted in the wire. When the waves traversed the wire they gave rise to sparks as much as 6 millimetres long. A thin copper wire was then stretched across between two corresponding holes of the disks. On doing this, the length of the sparks sank to 3·2 millimetres. There was no further alteration if a thick copper wire was put in the place of the thin one, or if, instead of the single thin wire, twenty-four of them were taken, provided they were placed near each other through the same two holes. But it was otherwise if the wires were distributed over the rim of the disks. If a second wire was inserted opposite the first one, the spark-length fell to 1·2 millimetres. When two more wires were added midway between the first two, the length of the spark sank to 0·5 millimetres; the insertion of four more wires still in the mean positions left sparks of scarcely 0·1 millimetres long; and after inserting all the twenty-four wires at equal distances apart, not a trace of sparking was perceptible in the interior. The resistance of the inner wire was never-

theless much smaller than that of all the outside wires taken together; we have also a still further proof that the effect does not depend upon this resistance. If we place by the side of the partial tube of wires, and in parallel circuit with them, a conductor in all respects similar to that in the interior of the tube, we have in the former brilliant sparks, but none whatever in the latter. The former is unprotected, the latter is screened by the tube of wires. We have in this an electrodynamic analogue of the electrostatic experiment known as the electric birdcage. I again altered the experiment, in the manner depicted in Fig. 1. The two disks were placed so near together that they formed, with the wires inserted between them, a cage (A) just large enough for the reception of the spark-micrometer. One of the disks, α, remained metallically connected with the central wire; the other, β, was insulated from the wire by means of a circular hole through its centre, at which it was connected to a conducting-tube, γ, which, insulated from the central wire, surrounded it completely for a length of 1·5 metre. The free end of the tube, δ, was then connected with the central wire. The wire, together with its spark-gap, is once more situated in a metallically protected space; and it was only to be expected, from the previous experiments, that not the slightest electrical disturbance would be detected in the wire in whichever direction waves were sent through the apparatus. So far, then, this arrangement promises nothing new, but it has the advantage over the previous one that we can replace the protecting metallic tube, γ, by tubes of smaller and smaller thickness of wall, in order to investigate what thickness is still sufficient to screen off the outside influence. Very thin brass tubes, tubes of tinfoil and Dutch metal proved to be perfect screens. I now took glass tubes which had been silvered by a chemical method, and it was then perfectly easy to insert tubes of such thinness that, in spite of their protecting power, brilliant sparks occurred in the central wire. But sparks were only observed when the silver film was no longer quite opaque to light and was certainly thinner than $\frac{1}{100}$ millimetre. In imagination, although not in reality, we can conceive the film drawn closer and closer round the wire, and finally coinciding with its surface; we should be quite certain that nothing would be radically altered thereby. However actively, then, the real waves play round the wire its interior remains completely at rest; and the effect of the waves hardly penetrates any more deeply

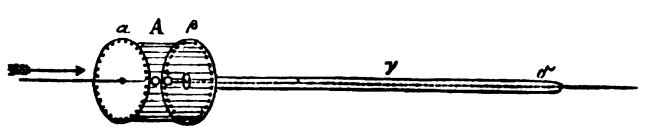

FIG. 1.

into the interior of the wire than does the light which is reflected from its surface. For the real seat of these waves we ought not to look, therefore, in the wire, but rather to assume that they take place in its neighbourhood; and instead of asserting that our waves are propagated in the wire, we should be more accurate in saying that they glide along on the wire.

Instead of placing the apparatus just described in the circuit in which we introduced waves indirectly, we can insert it in one branch of the primary conductor itself. In such experiments I obtained results similar to the previous ones. Our primary oscillation, therefore, takes place without any participation of the conductor in which it is excited, except at its bounding surface; and we ought not to look for its existence in the interior of the conductor.*

To what has been said above about waves in wires we wish to add just one remark concerning the method of carrying out the experiments. If our waves have their seat in the neighbourhood of the wire, the wave progressing along a single isolated wire will not be propagated through the air alone; but since its effect extends to a great distance it will partly be transmitted by the walls, the ground, &c., and will thus give rise to a complicated phenomenon. But if we place opposite each pole of our primary conductor in exactly the same way two auxiliary plates, and attach a wire to each of them, carrying the wires straight and parallel to each other to equal distances, the effect of the waves makes itself felt only in the region of space between the two wires. The wave progresses solely in the space between the wires. We can thus take precautions to propagate the effect through the air alone or through another insulator, and the experiments will be more convenient and free from error by this arrangement. For the rest, the lengths of the waves are nearly the same in this case as in isolated wires, so that with the latter the effect of the disturbing causes is apparently not considerable.

* The calculation of the self-induction of such conductors on the assumption of uniform density of current in their interior must therefore lead to quite erroneous results. It is to be wondered at that the results obtained with such wrong assumptions should still appear to approximately coincide with truth.

3. We can conclude from the above results that rapid electric oscillations are quite unable to penetrate metallic sheets of any thickness, and that it is, therefore, impossible by any means to excite sparks by the aid of such oscillations in the interior of closed metallic screens. If, then, we see sparks produced by such oscillations in the interior of metallic conductors, which are nearly, but not quite, closed, we shall be obliged to conclude that the electric disturbance has forced itself in through the existing openings. This view is also correct, but it contradicts the usual theory in some cases so completely that one is only induced by special experiments to give up the old theory in favour of the new one. We shall choose a prominent case of this kind, and by assuring ourselves of the truth of our theory in this case, we shall demonstrate its probability in all other cases. We again take the arrangement which we have described in the previous section and drawn in Fig. 1; only we now leave the protecting tube insulated from the central wire at δ. Let us now send a series of waves through the apparatus in the direction from A towards δ. We thus obtain brilliant sparks at A; they are of similar intensity to those obtained when the wire was inserted without any screen. The sparks do not become materially smaller, if, without making any other alteration, we lengthen the tube γ considerably, even to 4 metres. According to the usual theory it would be said that the wave arriving at A penetrates easily the thin, good-conducting metal disc α, then it leaps across the spark-gap at A, and travels on in the central wire. According to our view, on the contrary, we must explain the phenomenon in the following manner:—The wave arriving at A is quite unable to penetrate the metallic disc; it therefore glides along the disc over the outside of the apparatus and travels as far as the point δ, 4 metres away. Here it divides: one part, which does not concern us at present, travels on immediately along the straight wire, another bends into the interior of the tube and then runs back in the space between the tube and the central wire to the spark-gap at A, where it now gives rise to the sparking. That our view, although more complicated, is still the correct one, is proved by the following experiments:—Firstly, every trace of sparking at A disappears as soon as we close the opening at δ, even if it be only by a stopper of tinfoil. Our waves have only a wavelength of 3 metres; before their effect has reached the point

FIG. 2.

δ the effect at A has passed through zero and changed sign. What influence, then, could the closing of the distant end δ have upon the spark at A, if the latter really happened immediately after the passage of the wave through the metallic wall? Secondly, the sparks disappear if we make the central wire terminate inside the tube γ, or at the opening δ itself; but they reappear when we allow the end of the wire to project even 20 to 30 centimetres only beyond the opening. What influence could this insignificant lengthening of the wire have upon the sparks in A, unless the projecting end were just the means by which a part of the wave breaks off and penetrates through the opening δ back into the interior? Thirdly, we insert in the central wire between A and δ a second spark-gap B, which we also completely cover with a gauze cage like that at A. If we make the distance of the terminals at B so great that sparks can no longer pass across, it is also no longer possible to obtain visible sparks at A. But if we hinder in like manner the passage of the spark at A, this has scarcely any influence on the sparks in B. Therefore the passage of the spark at B determines that at A, but the passage of a spark at A does not determine that at B. The direction of propagation in the interior is therefore from B towards A, not from A to B.

We can moreover give further proofs, which are more convincing. We may prevent the wave returning from δ to A from dissipating its energy in sparks, by making the spark-gap either vanishingly small or very great. In this case the wave will be reflected at A, and will now return again from A towards δ. In doing so, it must meet the direct waves from δ to A and combine with them to form stationary waves, thus giving rise to nodes and ventral segments. If we succeed in proving their existence, there will be no longer any doubt as to the truth of our theory. For this proof we must give somewhat different dimensions to our apparatus in order to be able to introduce electric resonators into its interior. I therefore led the central wire though the axis of a cylindrical tube 5 metres long and 30 centimetres diameter. It was not constructed of solid metal, but of 24 wires arranged parallel to each other along the generating surface, and resting on seven equidistant and circular rings of strong wire, as shown in Fig. 2. I made the requisite resonator in the following manner:—A closely-

Digitized by Google

wound spiral of 1 centimetre diameter was formed from copper wire 1 millimetre thickness; about 125 turns of this spiral were taken, drawn out a little, and bent into a circle of 12 centimetres diameter: between the free ends an adjustable spark-gap was inserted. Previous experiments had shown that this circle responded to waves 3 metres long in the wire, and yet it was small enough in size to admit of its insertion between the central wire and the surface of the tube. If now both ends of the tube were open, and the resonator was then held in the interior in such a way that its plane included the central wire, and its spark-gap was not directed exactly inwards or outwards, but was turned towards one end or the other of the tube, brilliant sparks of $\frac{1}{2}$ to 1 millimetre length were observed. On now closing both ends of the tube by four wires arranged crosswise and connected with the central conductor, not the slightest sparking remained in the interior, a proof that the network of the tube is a sufficiently good screen for our experiments. The end of the tube on the side β, that, namely, which was furthest away from the origin of the waves, was now removed. In the immediate neighbourhood of the closed end, that is at the point a, which corresponds to the spark A of our previous experiments, there were now no sparks observable in the resonator. But on moving away from this position towards β, sparks appeared, became very brilliant at a distance of 1·5 metre from a, then decreased again in intensity, they almost entirely vanished at 3 metres distance from a, and increased again until the end of the tube was reached. We thus find our theory borne out by fact. That we obtain a node at the closed end is clear, for at the metallic contact between the central wire and the surface of the tube the electric force between the two must necessarily vanish. It is different when we cut the central conductor at this point just near the end, and insert a gap of several centimetres length. In this case the wave will be reflected in a phase opposite to that of the previous case, and we should expect a ventral segment at a. As a matter of fact we find brilliant sparks in the resonator in this case; and they rapidly decrease in strength if we move from a towards β, they almost entirely vanish at a distance of 1·5 metre, and become brilliant again at a distance of 3 metres; moreover they give a second well-marked node at 4·5 metres distance, that is 0·5 metre from the open end. The nodes and loops which we have described are situated at fixed distances from the closed end, and alter only with this distance; they are, however, quite independent of the occurrences outside the tube, for example, of the nodes and loops formed there. The phenomena occur in exactly the same way if we allow the wave to travel through the apparatus in the direction from the open to the closed end; their interest is, however, smaller, since the mode of transmission of the wave deviates from that usually conceived, less in this case than in the one which has just been under our consideration. If both ends of the tube are left open with the central wire undivided, and stationary waves with nodes and loops are now set up in the whole system, there is always found, for every node outside the tube, a corresponding node in the interior; which proves that the propagation takes place inside and outside with, at any rate approximately, the same velocity.

On looking over the experiments which we have described, and the interpretation put upon them, as well as the explanations of the physicists referred to in the introduction, a difference will be noticed between the views here put forward and the usual theory. According to the latter, conductors are represented as those bodies which alone take part in the propagation of electric disturbances; non-conductors are the bodies which oppose this propagation. According to our view, on the contrary, all transmissions of electrical disturbances is brought about by non-conductors; conductors oppose a great resistance to any rapid changes in this transmission. One might almost be inclined to maintain that conductors and non-conductors should, on this theory, have their names interchanged. However, such a paradox only arises because one does not specify the kind of conduction or non-conduction considered. Undoubtedly metals are non-conductors of electric force, and just for this reason they compel it under certain circumstances to remain concentrated instead of becoming dissipated, and thus they become conductors of the apparent source of these forces, electricity, to which the usual terminology has reference.

Karlsruhe, March, 1889.

ELECTRICAL STANDARDS.*

As a general rule, the most convenient method of obtaining the absolute value of any magnitude is to compare it with a *standard*—that is to say, with a magnitude of a similar kind whose value is unity or some known multiple of unity. Therefore, in precise measurements, the choice of standards and the determination of them in absolute values has a very great interest attaching to it. It is easy to see how a conductor standardised at a constant temperature can furnish a standard resistance, how a condenser of known capacity can furnish a standard capacity; but there are magnitudes, such as the strength of a current or a quantity of electricity, of which it is difficult to have true standards. In these cases the difficulty is got over by having instruments which always give the same indication when traversed by currents of the same strength, and these instruments, which serve the purpose of a true standard, deserve the name of *standard instruments*.

In electro-magnetic measurements (the only ones with which we need concern ourselves here) there are only three magnitudes of which the values in absolute units can be obtained directly; these are:—

1. The coefficients of mutual induction or of self-induction, of which the value can be obtained by simple measures of length (dimensions [L]).

2. The resistance of a conductor, the value of which can be given by measures of length and of time (dimensions $[L T^{-1}]$).

3. The strength of a current, the value of which can be given by the measure of a force and by measurements connected with length (dimensions $[F^{\frac{1}{2}}] = [L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1}]$).

Also the standards of these three magnitudes are suitably called the *primary standards*, for these are the only ones whose values can be easily ascertained without having recourse to other electrical standards. On the other hand, the standards of the other electrical magnitudes, which, in practice, reduce to the standards of electromotive force and capacity, will be called *derived standards*.

Primary Standards.

1. *Standards for Coefficients of Mutual Induction and of Self-Induction.*—We will confine ourselves to remarking that it would be useful to have standards for coefficients of mutual induction. Such standards do not yet exist, or, at least, are not common in laboratories.

2. *Standard Resistances.*—In 1882 the International Conference on Electrical Units in its first session decided that a standard resistance having the value of an ohm should be constructed, and invited the assistance of the *savants* of the different countries represented at the Conference in order to decide what length should be given to column of mercury at 0°C., having one millimetre square section, in order that it should represent the theoretical ohm (10^9 C.-G.-S. units). In its second session, in 1884, after having reviewed the work done on this subject,* it fixed the length at 106 centimetres. The legal ohm *is the resistance of a column of mercury having a sectional area of one square millimetre and a length of* 106 *centimetres at the temperature of melting ice.*

M. Benoît, at the International Bureau of Weights and Measures, has constructed in mercury, for the Minister of Posts and Telegraphs, four model standards, representing the legal ohm.† Each of these standards consists of a rectilineal glass tube, having a sectional area of about one square millimetre, whose ends open into large containing vases, which, together with the tube, are filled with very pure mercury. The whole rests on a brass base, which allows the apparatus to be plunged in melting ice or of its being put into a bath at a known temperature. The glass tube has been calibrated, and gauged with all attainable accuracy, and cut to such a length that the standard shall represent the legal ohm, due allowance being made in construction for the correction in length necessary owing to the spreading out of the lines of force in the mercury of the vases. In addition, M. Benoît has constructed, for the Minister of Posts and Telegraphs, a great number of secondary standards, formed of a glass tube, five times bent back on itself in vertical bends, and terminated by two large tubes forming funnels, which, together with the narrow tube, are full of mercury. The resistance of these secondary standards has been obtained by electrical comparison with the model standards. These secondary standards have served to calibrate the metallic resistances of the French makers.

They proceeded differently in England. The specific resistance of mercury had been determined as a function of the ohm of the British Association by many physicists, amongst others by Lord Rayleigh and Mrs. Sidgwick.‡

Following this determination the Committee of the British Association has taken

1 legal ohm = 1·0112 B.A.U.

The English legal ohm has a slightly higher resistance than the French; the difference is $0{\cdot}0005\omega$, taking the figures given by Mr. R. T. Glazebrook.§

In a recent work on the specific resistance of mercury, Messrs. Glazebrook and Fitzpatrick‖ have compared the original standard ohms of the British Association¶ with the resistance at 0°C. of a column of mercury one metre in length, and whose sectional area was one square millimetre. They find that the resistance of this column of mercury is 0·95352 B.A.U., and consequently

1 legal ohm = 1·0107 B.A.U.

Taking this result, the English legal ohm is too great by $0{\cdot}0005\omega$, and the French legal ohm is accurate.

The standard resistances of Messrs Siemens and Halske,* which have been constructed to represent the resistance at 0°C. of a column of mercury one metre long and one square millimetre sectional area, have served the German makers as a basis for obtaining the legal ohm ; they have taken

1 legal ohm = 1·06 Siemens' unit.

Siemens and Halske's standard has been subjected to several comparisons with the mercury standards of different experimenters ; the results are as follows :—

Experimenters.		
1882.....	Lord Rayleigh and Mrs. Sidgwick.....	0·99949†
1884.....	Roïti	0·99997†
1884.....	Mascart, de Nerville and Benoit	1·00003†
1884.....	Strecker (mean of two Siemens' standards)	1·00017†

From this table we see that Messrs. Siemens and Halske's standards agree well with the other mercurial standards if we take into account the slight error in the experiments of Lord Rayleigh and Mrs. Sidgwick which seems to exist if we follow the work of Messrs. Glazebrook and Fitzpatrick, and which would nearly bring the first numbers given in the table up to unity.

The mean of the numbers presented to the 1884 Conference as the length of the column of mercury representing the true ohm is 106·04. The mean of the numbers obtained by the method of lowering the current strength gives a mean decidedly lower than that furnished by the other methods. M. Mascart‡ has since shown that this method requires several corrections which have not been made, and which tend to raise the number. Suppressing the numbers due to the method of lowering the current strength, the mean rises to 106·15. A discussion of the methods employed still further raises the number, and would bring it up to 106·25.

Since 1884 a fairly large number of other determinations of the ohm are nearly all in agreement in furnishing numbers close to 106·30 (the number brought to the Conference in 1884 by MM. Mascart, de Nerville and Benoît ; by Mr. Glazebrook and Lord Rayleigh, 106·28). Amongst these experiments we ought to mention those of Prof. Rowland,§ made under most favourable conditions, and which give the figure 106·32 ; the experiments of F. Kohlrausch‖ (106·32), and the quite recent ones of M. Dorn¶ (106·24) made by the method of lowering the current and corrected ; the experiments of M. Wuilleumier** (106·27) made by the excellent modification of Lorenz's method suggested by M. Lippmann.

To sum up, these different measurements agree in showing that in taking 106·30 as the length of the column of mercury representing the theoretical ohm there is probably only an error of less than $\frac{1}{3000}$.

3. *Standards for Current Strength.*—As a general rule, the absolute value of the strength of an electrical current is measured by one of the three following methods :—1. The tangent galvanometer method ; 2. Kohlrausch's method ; 3. The electro-dynamometer methods, and principally by electro-dynamometer balances. These latter instruments give the current strength by weighing it, using the formula $i = A\sqrt{pg}$, where p is the number of grammes in the weight (pg) which balances the electro-dynamic force, and A is a constant depending on the form of the instrument and determined by measures of lengths ; these latter may be made by an arbitrary unit, since it only enters into the expression A in the ratio of the lengths. The electro-dynamometer balances thus come into the category of standard instruments. On account of the simplicity of measurement with these instruments a greater accuracy can be obtained than with other methods.

MM. Joule, Cazin, Mascart, Helmholtz, &c., have constructed balances for the purposes of special researches ; each of these instruments seems capable of serving as an original model standard, but no copy has been made. There are, however, standard instruments giving the absolute value of the current strength. Sir W. Thomson is the inventor of a series of electrical balances, designed, some to measure weak currents (milli-ampere, centi-ampere), others to measure currents of a deci-ampere or an ampere ; others, again, for currents of a hundred amperes up to a thousand amperes. These instruments are widely distributed in England and in some other countries.

In France M. Pellat†† has had constructed by M. Carpentier an electro-dynamometer-balance which differs from those employed till then in that the small coil with vertical axis is in one with the beam of the balance and is placed in the centre of a long horizontal coil. The small coil having only one turn of wire, and being far from the ends of the large coil, the irregularities of winding which always occur at the ends of a coil of many turns of wire are here without effect. The necessary measures of length required to determine the constant A were made, through the courtesy of the International Bureau of Weights and Measures. Taking all the possible errors in the measurements and adding them together we find that the error made in the constant A cannot exceed $\frac{1}{3000}$. Moreover, the error due to the weights is very trifling.

Further, M. Pellat* has had constructed by M. Carpentier copies of his absolute electrical balance, to which he has given the name of standard ampere balance ; they only differ from the former instrument in that the moving coil has several turns of wire and the fixed coil is much shorter. The constant A of the standard ampere balance was determined by comparison with the absolute electro-dynamometer ; this determination was made with an accuracy of $\frac{1}{10000}$. The constant A is absolutely independent of temperature.

Derived Standards.

1. *Standards of Electromotive Force.*—A cell furnishes a standard of electromotive force. The absolute value of the difference of potential between the two terminals of the cell on open circuit, which is the measure of its electromotive force, is determined by comparing it with the difference of potential e which exists at the ends of a known resistance traversed by a known current i ($e = ir$). The comparison may be made either by charging a condenser, or, which is much more accurate, by opposing the cell and the electromotive force developed at the ends of the resistance by the passage of the current, and varying this until the two electromotive forces are equal. Unfortunately no cell studied by the exact method above described possesses an electromotive force which does not vary in time.

The cells which are most employed as standards are the copper-sulphate Daniell, or its different modifications (Callaud's, the Post Office standard, &c.), the Latimer Clark sulphate of mercury cell, and Gouy's cell with bionxide of mercury. Unless very great precautions are taken in its setting up and in its maintenance,† the Daniell is useless as a standard where great accuracy is required. The electromotive force of cells of the same construction but with elements from different sources may vary from 1·06 volt to 1·14 volt at least. And more serious still, the inevitable changes taking place on the surfaces of the metal electrodes prevent the electromotive force remaining constant when the cell is set up. The best way of having a Daniell whose electromotive force shall be nearly constant is to set it up with new solutions before using it, and close the circuit for some time so as to coat the copper electrode with copper ; the cell should then be left on open circuit for some minutes before using it as a standard.

The Latimer Clark and the Gouy, in which pure amalgamated zinc and mercury are used as electrodes, are far preferable. The metals do not alter, or, at least, the alteration which takes place in lapse of time on the surface of the zinc does not affect the electromotive force. The Latimer Clark may be constructed in one of two different ways : (1) by using as an electrolyte a paste formed of mercurous sulphate soaked in a solution of zinc sulphate; (2) by employing a weak (say 15 per cent.) solution of sulphate of zinc and spreading the mercurous sulphate in a powder on the surface of the mercury.‡ According to the unpublished work of Messrs. Potier and Pellat, the liquid Latimer Clark (1·466 volt mean) is preferable to the Latimer Clark with a pasty electrolyte. The electromotive force varies less with time ; the coefficient of variation for temperature is about half that of the other, and its temperature can be known accurately, which is impossible with a pasty electrolyte. Fiually the cell is a better conductor and polarises very little on the passage of the current.

Several liquid Latimer Clark's, constructed almost at the same time, do not differ as a rule by more than $\frac{1}{1000}$ from their mean value at the same temperature, unless by some accident the mercury has touched the zinc ; traces of zinc in the mercury are sufficient to diminish the electromotive force considerably ; it may even be annulled or reversed. The Gouy cell§ (1·390 mean voltage) is as remarkable for its constancy as the Latimer Clark ; it only differs from the liquid Latimer Clark by the substitution of oxide of mercury for mercurous sulphate in the electrolyte. This alteration has an advantage and a disadvantage ; the advantage is that the variation of the electromotive force for change of temperature is reduced to nearly one-half (0·0014 about) ; the inconvenience is that the depolariser is less efficacious, and therefore the polarisation of the Gouy cell is much greater and takes longer to disappear than in the case of the liquid Latimer Clark.

Different Gouy cells prepared with substances from the same source do not differ as a rule by more than $\frac{1}{100}$ from their mean value.

To sum up, either the Latimer Clark or the Gouy cell might be of great use, even in researches requiring the greatest accuracy ; but for this we must have a thermometer with its bulb plunged in the electrolyte to give the temperature of the cell. We ought besides from time to time to measure the absolute value of the electromotive force of the standard, and to compare its value frequently with similar standards placed under similar conditions as to temperature in order to be sure that the electromotive force has not varied by a sensible amount owing to some accident.

One of the principal uses of a standard of electromotive force whose absolute value is known is to measure quickly and accurately a weak or strong current by the opposition of this standard to the electromotive force set up by it at the two ends of some suitable known resistance—by reversing the operation, in fact, which served to determine the absolute value of the cell. Together these two operations constitute the most simple and exact

* The mercury standards of M. Siemens were first constructed in 1868. In 1881 to 1882, the old standards having nearly all disappeared by a series of accidents, a very careful reconstruction of mercurial standards was made with rectilineal glass tubes, gauged and calibrated by the Imperial Commission of Weights and Measures at Berlin. It is these new standards which are referred to above.

method of comparing the value of a known current (taken on electric dynamometer balance) with the value of a current of very different strength.

2. *Standards of Capacity.*—The standards of capacity are condensers graduated in microfarads and fractions of a microfarad; they are made of tinfoil, or sometimes tinsel, alternating with some insulating substance. This insulating substance varies with the makers; those substances most often employed being mica, paraffined mica, paper paraffined or covered with some other insulating material, finally ebonite cut down into very thin leaves. The standards of capacity are still much more imperfect than the standards of electromotive force. These all show three great faults in a greater or less degree: (1) The charge is not rigorously proportional to the difference of potential of the plates; (2) they have a residual charge; (3) the insulation is imperfect. Moreover, the capacity varies fairly rapidly with the temperature.

When a condenser has a residual charge, its capacity is only strictly accurate in two cases—that in which discharge follows charge so rapidly that there is no penetration of the electricity into the dielectric, and that in which the charge lasts sufficiently long for the penetration to have attained its maximum. But when using condensers it is often difficult to realise these conditions. As an instance, if we wish to measure the charge on a condenser by discharging it through a galvanometer and noting the swing of the needle we make use of a formula which is only exact if the discharge takes place in so short a time that the needle has not moved sensibly while it lasts; now this does not happen if the penetration has attained its maximum, since the total discharge requires a time comparable to that of charge.

An air condenser is the only condenser which could be considered a true standard. Unfortunately it would appear difficult to obtain an air condenser of a capacity of about a microfarad of a convenient size, since two circular plates 60 centimetres in diameter and distance apart 0·025 centimetre form a condenser of about $\frac{1}{100}$ microfarad capacity.

The determination of the absolute value in electro-magnetic units of a capacity is made most often by methods in which the capacity is referred to that of a resistance and a time, as in Maxwell's method,* or its modifications by J. J. Thompson† and R. T. Glazebrook‡; or, better, by the methods in which the measure of the capacity is referred to that of a resistance and a coefficient of mutual induction, such as that employed by M. Roïti in the study of the different condensers displayed at the Antwerp§ Universal Exhibition.

The measures of M. Roïti and of other physicists show that the real value of the capacities found in commerce rarely differ by less than 1 per cent. from their nominal value, and that often the error rises to 4 per cent.

In concluding this report on electrical standards, we may be allowed to express a wish.

The standards of mutual induction, of resistance, and of current strength, which we have called the *primary standards*, because their absolute value can be separately determined without having recourse to other electrical standards, show when suitably made an invariability similar to that of a standard of length or of mass.

The necessity of establishing a legal standard of resistance has been recognised, why should the same not apply to the other two principal standards?

The question is of especial importance in connection with current strength, and would seem now to be sufficiently matured. The International Bureau of Weights and Measures possesses already original standards of length, mass, and electrical resistance; it seems quite designed to take charge of an electro-dynamometer balance, which should serve as a model standard instrument for the measure of current strengths, and by it other instruments could be standardised.

Currents measured by the model electro-dynamometer by the formula $i = A\sqrt{p\,g}$, where A represents the constant of the instrument determined by measures of length, would give the value of a conventional ampere, which would only differ from the theoretical ampere by a quantity which would certainly be less than that by which the legal ohm differs from the true ohm; it is very probable the error would be less than $\frac{1}{2000}$. Moreover, we should have in M. Pellat's absolute electro-dynamometer a check on the readings of this instrument. Many people will think that for the purpose of comparing currents it would be more simple to take the mass of silver deposited in one second by an ampere. We must remark that the conventional ampere thus fixed would not be defined with sufficient precision; in fact, electrolysis is an extremely delicate operation, the sources of relative error in which are ten times greater than in the case of the comparison of two electro-dynamometer balances. Thus, the following are the last results obtained for the electrolytic equivalent of silver:—

	Mass of silver in milligrams deposited by 1 amp. in 1sec.
F. and W. Kohlrausch (‖)	1·1183 milligrams
Mascart (¶)	1·1156 „
Lord Rayleigh (**)	1·1179 „
MM. Potier and Pellat (††) { 1 determination	1·1189 } 1·1193 „
MM. Potier and Pellat (††) { 2 „ „	1·1195 }

Now, the differences which we find between the numbers on this table are not much greater than the same experimenter finds between the two electrolytic experiments made under as exactly similar conditions in all respects as possible. On the other hand, we have said higher up that the comparison between two electrical balances can be made with an accuracy of $\frac{1}{1000}$. This comparison shows clearly the inconvenience of a conventional ampere founded on electrolysis.

THE MEASURE OF ILLUMINATION.*

BY W. H. PREECE.

Photometry is the art of measuring the intensity of a source of light, such as an arc lamp, by direct comparison with some known source such as the carcel bec or British candle taken as unity; but the measure of the illumination of a surface, as far as intensity is concerned, is quite independent of the source of light itself, and it depends only on its distribution. The illumination of the page of the book we read, or of the paper on which we write, or the face which we address, or of the picture we admire, of the surface of the street on which we walk, varies in intensity whether the source of light which is distributed on these surfaces is the sun, the moon, or combustion, or incandescence of a carbon filament by currents of electricity, or whether it be single like daylight or multiplied like a well-planned electric light installation.

The standard that I propose is the intensity of illumination produced by a carcel lamp at a distance of one metre. This gives excellent illumination on the surface of a book. It is the same illumination as that given practically by a British candle at one foot distance, and thus it assimilates the English and French measures. I call this unit a "*LUX*," and I find that the illumination of the surface of a street lighted by a single ordinary gas burner is ·1 *lux*, while that due to an ordinary arc lamp is 1·8 *luces* if the measurement be made at the foot of the pole carrying the source of light.

In determining the illumination of the streets of a town I specify that the light shall be uniformly distributed over the surface of the street, and that the mean illumination shall not be less than three *lux*, and in the case of a room the light on any table in any part of the room should not be less than one *lux*, and this can be obtained by an expenditure of energy in glow-lamps in the ratio of about ten watts to one square metre floor surface. Hence a table of 100 square metres would take 1,000 watts, or 20 glow-lamps of 100 volts and five amperes or of 50 watts each well distributed to give a uniform illumination of about one *lux* on the level of the tables.

The measurement of this illumination is very simple. A small glow-lamp is placed inside a box, the top of which has a screen of white paper, on which is made a grease spot. The illumination of this grease spot on the inside is varied by varying the current incandescing the glow-lamp. The strength of this current is the measure of the light. The intensity of the current producing a *lux* is first determined in the laboratory, and then the illumination of any spot that it is desired to measure is afterwards found by measuring the amperes, which cause this grease spot to disappear at that point. A simple calculation based on the law that within limits the light given by an incandescent carbon filament varies as the 1^6 gives the *luces* directly from the current read on a simple, but delicate amperemeter.

* Paper read before the Paris Electrical Congress, 1889.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 31, 1889.

The rise and fall of Mr. Harold P. Brown promises to be one of the most interesting and sensational episodes of late years in the electrical business in America. By this time your readers are probably pretty well acquainted with the doings of this gentleman, and will, therefore, not need a very long recital of his achievements. Some months ago Mr. Brown came to the front by writing letters to the daily papers attacking the alternating current, and particularly the Westinghouse apparatus. Previous to that time Mr. Brown had been engaged in various electrical pursuits, and had brought out one or two minor inventions, but did not in any way distinguish himself. When he began to write to the newspapers on the subject of the alternating current he had a great deal to say about the demerits of the Westinghouse apparatus, but as there was little else of the kind in the commercial field at that time this peculiarity did not attract much attention, it being taken for granted that the apparatus was spoken of as typical. A

Digitized by Google

little bit later the question of electrical execution came to the front, and when discussion arose as to the manner in which it was to be administered, Mr. Brown advanced the proposition that the Westinghouse apparatus was just the thing for the purpose. It was at this juncture that people began to grow suspicious as to what Mr. Brown's motives were, because there was no special reason why any particular apparatus should be chosen or designated, it being easy enough for any competent electrical engineer to devise special alternating apparatus for the purpose without giving it any name, or without in any way injuring any company or system that might be upon the market. Thus the matter drifted along until all the experiments and discussions on the subject wound up with the actual purchase by Mr. Brown of Westinghouse alternating machines for the State, to be delivered at the various prisons where criminals under sentence of capital punishment were kept. Of course, it was not to be expected that the Westinghouse Company would sell its machines for any such purpose as this, and Mr. Brown had therefore to make his purchase in some underhand way. He did succeed, however, in getting the machines, and they were delivered to the prison authorities. In the meantime the renewed discussion of electrical execution and the appeal of the murderer Kemmler had led to an official investigation into the nature of death by electricity, and of the manner in which the electrical execution law had come to be adopted; and as I have recently recorded in my letters a vast amount of evidence was taken upon the subject. Of course, Mr. Brown was placed upon the stand. While there he bore himself with easy confidence, and stated that he was not in any way connected with any of the electric lighting companies. In other words, he was doing all this upon his own initiative from public-spirited motives. Mr. Bourke Cockran, who examined him, endeavoured to prove that he had had some pretty close connection with Mr. Edison, and had been engaged by the Edison Company to carry on this war against the alternating system. The effort, however, did not succeed very well, and those who thought that Mr. Brown had had some selfish purpose throughout, were left after all with only their conjectures. On Sunday last, however, the *New York Sun* lifted the veil of mystery, and revealed Mr. Harold P. Brown in a very striking and peculiar attitude. The *Sun* published on that day between forty and fifty letters exchanged by Mr. Brown with various companies and individuals in the electric business, and tending to show that Mr. Brown's interest throughout had been very much a pecuniary one. How the *Sun* got possession of these letters does not appear; but it is reasonable to infer that whoever got possession of them took them to the Westinghouse people, who in turn placed them at the disposal of the *Sun*, which has been very warm and strenuous from the first in its fight against the electrical execution law. These letters are written by Mr. Brown, Mr. Edison, Mr. A. E. Kennelly, Dr. Louis Duncan, of Johns Hopkin's University, and various officers of the Edison Company, the Thomson-Houston Company, and Frank Ridlon and Company, the latter concern being the one through which the secondhand Westinghouse apparatus was obtained. It is somewhat difficult to give a synopsis of this extraordinary correspondence, which covers so many points, but it may be stated that throughout Mr. Brown is shown in the position of asking for money or suggesting that money be paid to him, and actually receiving money for expert and other work from the State, from the Edison Company, and from the Thomson-Houston Company. In one of his letters he goes so far as to invite Mr. Edison to chip in to the extent of $5,000. But he does not appear to have obtained this amount, and thereupon, as far as can be discovered, ceases to have an interest in inviting the Edison people to "prick the Westinghouse bubble." Switching off from the Edison Company, he appears during the past summer to have devoted his energies to working up a connection with the Thomson-Houston Company, although upon just what grounds it does not clearly appear. He had already committed himself in favour of the use of the alternating current, and having carefully impressed the idea of the fatality of the alternating current on the public mind, considered that he was in a position to dictate terms to any company that had alternating-current apparatus, and that did not wish to have it used for execution purposes. Hence we find him writing to the Thomson-Houston Company upon two or three occasions that he was under tremendous pressure to use other than the Westinghouse apparatus, and that things might happen which would be very detrimental to the certain Boston interests. Anyhow, he did not fall back on the Thomson-Houston apparatus, but through Frank Ridlon and Company secured the Westinghouse apparatus that he was after, promising the Thomson-Houston Company that one of the sets thus secured, ostensibly for the State, should be sent to Johns Hopkins' University for testing as to efficiency by Dr. Louis Duncan, who does not seem to have had the slightest idea of the use to which he was being put. Mr. Brown appears to have tried to get the Thomson-Houston Company in the position of declaring that 1,000 volts alternating would be adequate for execution purposes, but the company in one of these letters come out in a flat-footed way, and say that they do not consider that such a current could be relied upon for extinguishing human life. I could touch upon a good many other points in this interesting and suggestive correspondence, but I think I have said enough to show Mr. Brown in the right light and in his true attitude. If I have not, it may suffice to add that in one of his letters he makes a statement, which has been contradicted, that he paid $275 for inserting his Westinghouse challenge in the New York newspapers, and that he planned, after the publication of his second challenge, to mail it to all electric lighting companies in the United States and Canada, and "to deluge any town with them where I learn the Westinghouse Company are trying to form a company." Such is the man, and such is the animus that have been allowed to dictate the choice of Westinghouse apparatus in this State for execution purposes. I need hardly say that after an exposure like this there is a very good chance of the public disgust leading to the repeal of the law, and even if it is not repealed, there is good reason to believe that the Westinghouse apparatus will not be employed for killing people by the State. There is a general sigh of relief in electrical circles at finding Mr. Brown thus shown up. People have not known what to make of him, or what to do with him, and he seems to have played his cards so cleverly as to have set various interests at loggerheads, and to have aroused and kept up animosities whose only result could be to benefit himself.

A great deal of interest is being taken at the present time in schemes for rapid transit. I do not mean ordinary railroad work with express trains, but systems which have lately been exploited which promise a speed of something like 80 or 100 miles an hour. Two of these have already been noted in these columns. One is the Portelectric system of Mr. Williams, in which the rapid transportation of parcels, mail matter, etc., is effected by sucking a carriage through a succession of helices mounted on a light elevated track. Another is the Weems' system, in which the inventor has a similar elevated track upon which he runs an electric car at a very high rate of speed, the armature of the motor driving directly upon the axles of the car. A short model of the Portelectric system has been exhibited in New York and Boston, and a track over one mile long is now to be erected at Dorchester, Mass., to show how it will work out in the open. This track will stand about six feet high, with numerous curves, grades, &c. The helices will be six feet apart, and the carriage 12 feet long, with a circular section of about 10 inches. The Weems' system, which has been tested on a short track near Baltimore, is said to have yielded a speed there of over two miles a minute, and is now to be brought near to New York and tested on a long experimental track on Long Island. Hence we shall soon know definitely about the real merits of these latest attempts to travel or send goods at a higher speed than the slow rate of 60 or 70 miles an hour, which is altogether too dilatory for America.

The application of electricity to the distribution of power is coming to the front in a remarkable manner, and one sees every day exemplifications of the manner in which electric motors are put to good use, showing their superiority over other machines. Some notable schemes are afloat for power distribution, and I have no doubt that a great many of them will be carried into effect. One of them proposes the installation of an electric-power plant in one of our large cities with the object of throwing out over 900

Digitized by Google

steam engines, which average about 37 horse-power in capacity. Water is abundant, and it is proposed that the plant shall be built up from units of 1,000 horse-power compound condensing Corliss engines. A fair grade of coal is obtainable at $1.50 per ton, delivered, while fuel oil can be contracted for at $1.10 per hundred gallons. The longest circuit which would have to be installed would not exceed five miles. The majority of the owners of the steam plants readily admit that the introduction of the motor would effect a considerable saving in the operating expenses of their works and factories, and they are ready to adopt the motor in order to secure its conveniences. Hence it does not seem at all unlikely that at a very early day we may actually see a model central station power-plant of 40,000 horse-power capacity in full working order in the locality referred to. The great probability is that the load could be carried by a central station of much smaller capacity, but with a plant of 40,000 horse-power an immense amount of miscellaneous manufacture could be done, and manufacturers would be stimulated to increase their outputs to the fullest extent.

Another field in which we see a rapid introduction of the electric motor is that of mining, in which, I think, we are on the eve of great development in this country. It appears that Mr. Elmer A. Sperry, who has paid especial attention lately to the development of electric coal cutters, has met with excellent success. Some of his machines are now at work at Streeter, Ill., in a large coal mine on a circuit 8,000ft. long, and their working is so satisfactory that ten more machines are to be installed at the same place, while apparatus has also been ordered for Kewanee, Ill., Brazil, Ill., and Victoria, British Columbia.

Gas companies in various parts of the country are more and more finding a good practical utilisation of their gas in running gas machines to operate dynamos with. Several companies in the West are obtaining good results in this way. Thus, for example, at Iowa City, Iowa, a 20 horse-power Otto gas engine is running 16 arc lights on a three-mile street circuit, and the plant is to be increased. At Racihe, Wis., the gas company is running two Ottos, operating 62 Brush lamps of 2,000 candle-power on an 11-mile circuit. At Grand Forks, Dakota, the gas company is installing a 20 horse-power and a 50 horse-power Otto engine to run a plant of arcs and incandescents. The manufacturers of gas engines in this country are quick to perceive the opportunities that this work offers them, and are encouraging this kind of development as much as possible.

The news of work in the electric railway field is very encouraging, and now that the Fall approaches the companies are hustling to the full extent of their ability to get work done. As soon as the winter shuts in, stopping new work in the higher latitudes, we shall see greater activity than ever in the South, where scores of new electric railways are starting into existence. Just now every section alike is busy under the call for new equipments of every size. Electric roads are now to be found in all parts of the country, and even the weird territory of Utah is not to be excepted, as the Sprague Company has just put a fine road in operation in Salt Lake City. The company has started out with an initial equipment of 10 new Stephenson cars, and the tract is 4½ miles long, while 9 miles will be in operation by 1st September. The road is to be, when finished, 20 miles long, and to have at least 20 to 30 cars, which will be run in trains, so that when a Mormon family go to take a ride they can all go together.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *September* 8, 1889.

The Vienna-Prague Trunk line was completed on the 6th inst., and the first trials were made on Saturday last. The line is 310 kilometres long, and of silicium and phosphor bronze-wire, and runs quite alone. The result is that the line is entirely free from noise. It was begun on July 20, finished to outside Prague by August 20, and the town line was finished on the 6th. Speaking was perfect with the Gower-Bell microphone in Prague to a Berliner in Vienna on the direct metallic circuit ending in Prague and Vienna in the Post Office buildings. Then three translators were tried, and experiments were made from a subscribers' station in Prague to the Prague Exchange, through the Exchange to the Post Office, then through the translator over the metallic circuit line to Vienna. The Van Rysselburghe translator was first used, and the result was not very good ; then the Bennett was used, and speaking was as perfect as it could be, though not quite as loud as on the direct line ; last, a German translator, Landgraf, was used, and this one gave the best results, speaking being quite perfect in every way, and somewhat louder than with the Bennett translator. On Sunday the experiments were continued, at first between the two post offices on the direct line with the Gower-Bell, Berliner, and Schäffler microphones, all three working very well. Then a Landgraf translator was used in Vienna, the Post Office in Vienna being connected through the Vienna Exchange to a subscriber's office, and speaking to the Prague Post Office was tried. Speech was clear, but decidedly low. Then the Van Rysselburghe translator was tried and worked better, but not so well by a long way as the same experiment tried the day before from the Prague subscribers' station to Vienna Post Office with Landgraf and Bennett translators. After this, metallic circuit line from Prague Post Office to Vienna subscribers' station *via* Vienna Exchange was tried, speaking being again perfect. On this followed the experiment of speaking from Prague subscribers' station to Vienna subscribers' station *via* Prague Post Office and Exchange and Vienna Post Office and Exchange, Vienna subscribers being connected in metallic circuit ; Prague subscribers' station single line through Landgraf translator in Prague Post Office. Speaking was first-rate. Lastly, both subscribers' stations were connected through translators—in Prague, Landgraf, in Vienna, Van Rysselberghe—passing as before through both post offices and exchanges. Speaking was perfectly clear but not very loud. The Vienna lines being mostly cables, had, of course, an influence.

The experiments were on the whole a very decided success, and will be continued until perfect working is secured. The three apparatus used, Berliner, Schaffler, and Gower-Bell proved to be good instruments. It is expected that the line will be opened to the public in about a week or ten days.

An experiment was made speaking from the Prague Post Office *viâ* Vienna Post Office to Brünn, connected with Vienna by a telegraph line adapted on the Van Rysselberghe system. Speaking was fairly clear.

CORRESPONDENCE.

DISTRIBUTION BY MEANS OF CONDENSERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Being away on business I found on returning, in your issue of August 2nd, some remarks of Mr. J. D. F. Andrews upon my system of distribution.

Having been at work upon this matter for some six years, I have collected considerable experience in it.

Now, with respect to the statement of Mr. Andrews that currents of 5—8 amperes at 600—700 volts cannot be interrupted without violent sparking, I might add that this is indeed the case, but only so long as the number of reversals is not properly chosen, and I confess that this has been one of the chief inconveniences to overcome, which has caused me hard work for years.

What Mr. J. D. F. Andrews says about (his) Fig. 1 (*The Electrician*, August 2nd, p. 330) is quite true *per se*, but it has no bearing upon Fig. 3 in my article (*The Electrician*, July 26th, p. 294), for the latter represents the variation of the *current*, as can be seen from the text, whereas Mr. Andrews' diagram shows the charge (say in coulombs), which attains its maximum when the current is zero.

Concerning the arrangement which Mr. Andrews shows in his Fig. 3, it may be easily seen that the general effect would be increased, but the plant efficiency (economical coefficient) considerably lessened, by reason of the fact that always only a small part of the whole is made active.

Finally, Mr. Andrews speaks about the use of condensers for lighting glow-lamps in series. There was a time when I made numerous experiments in this direction with continuous as well as with alternating currents. But they have turned out unserviceable in practice, and so I have abandoned that way. Of course the current may be held invariable by short-circuiting the lamps ; but Mr. Andrews has overlooked another fact, namely, that the candle-power of the remaining lamps in-

Digitized by Google

creases; and there would be only one way to keep the latter constant—that is, in decreasing the area of the condenser and consequently the current simultaneously with the number of burning lamps.—Yours, &c., DR. STEPHAN DOUBRAVA.

Brünn, Sept. 7, 1889.

AN IMPROVED LIGHTNING PROTECTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Bennet's logic is not good. He candidly tells us he knows nothing about the discarded bobbin protector of the Post-office; *he* does not agree with several of my concluding statements, which have nothing to do with the discarded bobbin protector; therefore my comparison of a portion of his invention—an improved lightning protector—with the said discarded bobbin protector must be worthless.

Here is Mr. Bennet's own description of the part of his protector which I likened to the old bobbin protector: ". . . consists of a coil of fine wire let into a rectangular slot in a *metal* earth-plate. The coil might with greater advantage be wound on a metal (non-magnetic) core, and be enclosed in a metal tube or box, and form part of, or be in contact with, the earth-plate." The discarded bobbin protector consisted of two fine insulated wires wound side by side around a brass cylinder, and encased in a brass tube. The tube and cylinder were joined electrically and to earth. Two wires were used, so that the protectors might do for terminal or intermediate stations. The modification of this protector, which is used in conjunction with a plain plate protector and a fine platinum wire on all Post-offices cable, so far as I am aware, has only one wire and is minus the outer tube.

I did not think it necessary in my last letter to describe the bobbin protector, as everybody who has any pretentions whatever to a knowledge of lighting protectors and their history knows the bobbin protector. It did good service in its day, the serious objection to it being that it broke down the circuit, and it has been entirely superseded for land lines by the plain plate protector with mica sheet. The Post Office electricians with a lengthened and varied experience have come to the conclusion that this plain plate protector is the most efficient. One of the objections to the serrated plate protectors I mentioned was that it had to be carefully protected from dust. Mr. Bennet says this is wholly imaginary. I do not think so, and I hardly think it is so imaginary as Mr. Bennet's suggest that some situations will be found too damp for the plain plate protector with mica sheet. I fancy if such a situation could be found the serrated protector would be of little avail. Damp dust, so far as I know, will conduct better than slightly damp mica. The dampest places in which protectors are used are the cable huts on the sea coast, and we have yet to learn that any hut has been found so damp as to impair the efficiency of the plain plate protector.

I might further mention that in *Journal* No. 71 of the Institute of Electrical Engineers there is an abstract on Lightning Discharges. The author of the Paper tested eight different protectors, including a serrated and a few plain plate protectors with the opposing surfaces at different distances. The conclusion which the experimenter arrived at was that the two metal plates with smooth surfaces one millimetre apart gave the most perfect protection.—Yours, &c.,

Aberdeen, 9th September, 1889. W. NOBLE.

BOOKS, &c., RECEIVED.

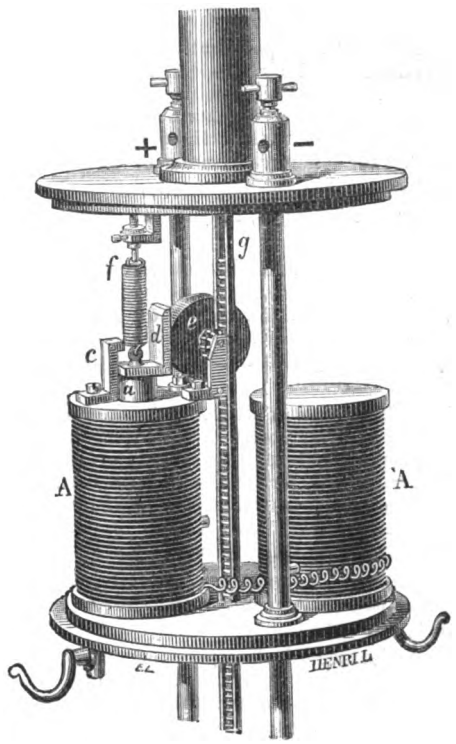
"Syllabus for the Twenty-second Session of the Leeds School of Science and Technology."

"The Steam Engine." A lecture by Edward N. Dickerson, LL.D., before the Electric Club of New York, January 17, 1889. (New York.)

Reduction of Telephone Subscriptions in France.—Consequent on the Government acquisition of the telephones the subscriptions are to be reduced from £24 to £16 in Paris, and from £16 to £12 and £8 in the provincial towns.

THE WENZEL ARC LAMP.*

The mechanism of the Wenzel lamp comprises a toothed rack, *g*, forming part of the positive carbon-holder and engaging with a small pinion, which is fixed to the iron drum *e*; a differential solenoid A, and a fine wire coil A', intended to increase the resistance of the shunt. The core *a* terminates in a square piece of metal, *d*, which rubs against the drum *e*, and it is held out of the solenoid by the spring *f*. A little catch *c* prevents *d* from rising beyond a certain point.



When the circuit is closed, the core *a* is sucked into the solenoid, and the head *d*, which is strongly magnetised, drags round the iron drum *e*, lifting the rack and striking the arc. When the length of the arc becomes excessive, the demagnetising effect of the shunt current allows the drum *e* to revolve, so that the positive carbon-holder descends. These movements are very regular and the lamp burns steadily.

THE E.M.F. DUE TO THE ACTION OF LIGHT ON SELENIUM.

In a recent number of Wiedemann's *Annalen* W. von Uljanin describes an interesting series of experiments on the E.M.F. produced by the action of light on selenium. Fritts, an American observer, had used gold leaf electrodes, but the gold leaf is very liable to peel off, and the author, therefore, discarded it in favour of platinised glass plates. Thin layers of platinum possess the additional advantage of allowing all the rays of the spectrum to pass with equal freedom. The selenium was melted in between the two plates, fixed parallel to each other, cooled under pressure, and then reduced from the amorphous to the sensitive crystalline form by being heated once or twice up to 195° in a paraffin bath, and then allowed to cool slowly.

The following experimental results were obtained:—

(1) The effect of exposing one of the electrodes to the action of light is to produce an E.M.F. from the dark to the illuminated electrode. The highest E.M.F. obtained was 0·12 volt, and it was always found to disappear completely and instantaneously when both electrodes were darkened. The difference in the behaviour of different plates was very slight.

(2) Plates prepared by other methods were found to give very variable results, some giving an E.M.F. in the same direction when

*Translated from M. Hippolyte Fontaine's "Éclairage à l'Électricité," by kind permission of the author.

Digitized by Google

either electrode was illuminated, but the effect was in these cases always greater when the negative electrode was the one exposed to the light.

(3) If the electrodes are kept joined through a wire for many hours the current from the dark to the illuminated electrode continues to flow with undiminished strength.

(4) When both electrodes are illuminated together the current can be weakened to any desired extent or reduced to zero.

(5) The action of light is instantaneous.

(6) Many of the plates were found to be subject to polarisation, but it had no effect on their sensitiveness to the production of E.M.F.

(7) When the E.M.F. of polarisation has attained a sufficiently high value it is diminished by the exposure of either electrode to the action of light. For smaller values of the E.M.F. the effect of light is of the normal character described under (1). The limiting value below which the effects of light were normal was found to vary considerably for different specimens.

(8) The resistance, and the sensitiveness to the production of E.M.F. when exposed to light, in general diminish gradually with lapse of time.

(9) Both the resistance and the sensitiveness to the production of E.M.F. are much increased by passing alternate currents from a small coil through the plates, and those which have lost their sensitiveness through lapse of time can be restored to their original condition by continuing this treatment for a sufficient length of time.

(10) With weak sources of light, and when the heat rays are excluded as completely as possible, the strength of the current is found to be proportional to the intensity of illumination of the electrode; but with stronger sources of light, without exclusion of heat rays, the current strength increases more slowly than the intensity of illumination. The E.M.F. in this case seems to increase more slowly than the conductivity.

(11) In the diffraction spectrum the orange-yellow rays were found to produce the greatest effect, and the greenish-yellow rays in the prismatic sprectrum.

The initial resistance of the specimens employed varied from 40,000 ohms to 900,000 ohms in the dark. The resistance of the specimen with the latter initial resistance gradually increased up to 1·4 megohm. The plates prepared by the author's method were found to be exceptionally sensitive to the action of light on their resistance, the effect of exposure to light being to diminish the resistance to about one-ninth of its initial value.

The author explains the results obtained on the hypothesis that the selenium in the plates exists in several allotropic forms, some only of which are sensitive to the action of light with respect to the production of E.M.F. He further supposes that some of the particles consist of combinations of different allotropic forms, or of selenides of the metals, of which traces existed in all the specimens experimented on. The effect of light he assumes to be to transform the sensitive particles into others electro-positive to them, and to facilitate the re-combination of the electrolytic molecules which have been taken up by the passage of the current.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

August 21, 1889.

13,154. T. MATHER and W. E. SUMPNER. London. Improvements in constructing or winding coils for electrical apparatus.

13,168. A. MCCANDLISH and S. H. HEYWOOD. Bredbury. Supporting electric lamps on the surfaces of iron or steel structures by means of a magnet, and preserving from abrasion its conductors.

13,172. F. V. ANDERSON. London. Improvements in conduits for laying underground electrical conductors, and in the means for supporting, guiding, and insulating the said conductors therein, and in clips for holding together the strips of conductors constructed of thin strips of metal.

13,183. J. RADCLIFFE. East Retford. Improvements in apparatus and in the combination thereof for lighting railway carriages, tramcars, and other vehicles by electricity.

13,191. T. A. D. FORSTER. United States. An electro-magnetic protector for electrical instruments.

August 22, 1889.

13,223. C. W. BEESLY. London. Improvements in electrodes and filaments for electric lamps, and in materials for the same.

13,273. C. JULIAN. London. Improvements in arc lamps.

13,282. G. F. SLATTER. London. Improvements in electric lamps, and means for securing electric lamps in carriages and like vehicles.

August 23, 1889.

13,323. W. SMETHURST. London. An improved method of carrying main leads and other electric wires along streets and other thoroughfares.

13,336. C. WELLS and J. BROWN. London. Improvements in electric arc lights.

August 24, 1889.

13,344. W. P. THOMPSON. Liverpool. Electro-therapeutic cap (T. Biermann, Germany).

13,382. M. BECKERS. London. An improved electric alarm or water level indicator, chiefly applicable to the water-gauges of steam boilers.

August 26, 1889.

13,444. F. REISINGER and W. WENZEL. London. Improvements in dynamo machines and the application thereof for regulating electric arc lamps and other purposes.

August 27, 1889.

13,459. G. DOWNING. London. Improvements in the construction of electric accumulators (J. F. Weyde and F. Clas, Austria, and J. Elsner, France).

13,480. W. P. KOOKOGEY. Glasgow. Apparatus for charging storage batteries and other purposes.

13,510. W. B. LAWRENCE. London. Lamp shades or reflectors for incandescent lamps.

13,541. C. R. BONNE. London. Improvements in electric wire and pole connectors (Messrs. Mix and Genest, Limited, Berlin).

CITY NOTES, &c.

CHILI TELEPHONE COMPANY.—Application has been made to the Stock Exchange Committee to appoint a settling day, and to grant a quotation for shares Nos. 1—40,000 of this company.

ENDOLITHIC IVORY COMPANY (LIMITED).—Registered on the 28th ult., with a capital of £10,000, in £1 shares, to establish manufactories for the process known as Dr. Hand Smith's "Endolithic process" for sinking and fixing colours, marks, and designs in, upon and under the surfaces of various substances.

INDIAN LIGHT RAILWAYS (LIMITED).—A company has been formed for the purpose of negotiating for permission to use any tramways or railways in India or elsewhere, and the rights, interests, and privileges of any concessions of tramways or railways which the company may deem necessary or convenient for any of its purposes. The company is registered by Clarke, Rawlins and Co., 66, Gresham House, E.C.

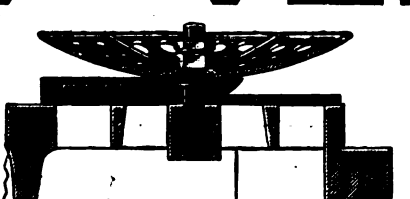
SCHMIDT-DOUGLAS ELECTRIC COMPANY (LIMITED).—An announcement is made in our advertising columns that the business of this company, now in liquidation, is to be sold as a going concern, together with the plant, &c., of the electric light stations at Bradford, Halifax and Leeds. Further particulars will be found in the advertisement.

BUSINESS NOTICE.—Mr. John Spencer, of the Globe Tube Works, Wednesbury, and of 3, Queen-street-place, Cannon-street, E.C., announces that he has *reduced* his discounts for wrought iron tubes and fittings 2½ per cent. on the gross. Mr. Spencer issues a neat and handy card price-list.

CHANGE OF ADDRESS.—The proprietors of our contemporary, *Industries*, have decided to establish their chief offices in London, at 358, Strand, W.C.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL." "12, John-street, Sunderland, 26th Sept., 1885.

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 592.—Vol. XXIII. FRIDAY, SEPTEMBER 20, 1889. Price Fourpence.

NOTES.

The highly successful meeting of the British Association which has just been brought to a close will not, in spite of its success, be memorable for any great advance in electrical science. The Newcastle meeting has been distinguished rather for the large number of electrical Papers possessed of high average merit, and bearing witness to the vast amount of patient detailed work which is being carried out, mainly in the laboratories of our technical colleges in all parts of the country. Papers of this description afford a welcome, though scarcely needed, demonstration of the vitality and of the thoroughness (so to speak) of Physical Science in the England of to-day, and "practical men" should, we think, heartily congratulate themselves on the existence of Institutions, and still more upon the unfailing supply of qualified men by whom such invaluable labours can be so successfully pursued. We do not, however, propose this week to offer any detailed comments upon the class of Papers to which we here more particularly allude. In our next issue we shall publish a "*Résumé* of the Electrical Papers read before Section A," from the pen of Dr. Oliver Lodge. Readers of *The Electrician* will not fail to remember the remarkable Paper, under the same title, which appeared in our columns at the close of the Bath meeting a year ago.

We shall, therefore, chiefly confine our remarks this week to the work of a more immediately practical kind, which has been brought before the Association this year. This leaves us with a fairly wide field for comment. Taking first the Papers read in Section A in chronological order from the list, which will be found in another column, we might, perhaps, be expected to say something about the Report of the Committee on the Magnetisation of Iron, and upon the Papers of Prof. Ewing relating to Hysteresis. The first of these was, however, merely preliminary and historical, and the second, though deeply interesting and important, dealt only with magnetisations which, from an engineer's point of view, may be considered microscopically small. We pass on to Tuesday morning, when Prof. Blyth exhibited a "New Form of Current Weigher." In this instrument, of which only rough models were shown, Prof. Blyth has endeavoured to overcome the difficulty of introducing the current into the moving coils by an ingenious application of the principle of the Roberval balance, in which the usual jointed connections are replaced by tightly-stretched torsion wires. The electrical connections are such that only one-half the current flows through any one torsion wire of the frame. In one pattern the coils are in a vertical plane, and the current is measured by the number of degrees of torsion that must be given to one end of one of the torsion wires in order to bring the balance to equilibrium. In this case the wire whose torsion rigidity is used to measure the current does not itself carry the current to be measured. It is obvious that the range of this type of instrument must be small compared with other types, since the limit of the permissible diameter of the torsion wires is soon arrived at, and any sensible heating of the wires would obviously introduce error. Prof. Perry exhibited some standards of self-induction—a piece of apparatus which is certainly fated to become more familiar to practical workers as time goes on.

We now come to what was beyond question the most important announcement (from the practical electrical standpoint) made during the meeting. This was nothing less than an entirely new and vastly simplified voltmeter, by Prof. Perry. We have for many years been in the habit of expecting (and obtaining) from Profs. Ayrton and Perry an improved voltmeter at intervals of about fifteen months. Writing without book, it is really impossible to recollect all the diverse types of volt and ammeter which have successively issued from the prolific laboratory of these Professors. We entertain, however, a lively recollection of the last occasion on which Prof. Ayrton displayed at the Institution a vast array of spider-web and bicycle-wheel diagrams, and announced the advent of the long-range-hot-short-wire voltmeter. It was a beautiful instrument, but we are, we believe, revealing no secret when we mention that six separate adjustments were required in its manufacture. This peculiarity could not be classed amongst the advantages of this type, and it may even go some way to account for its almost total absence from the open market. Great is the contrast betwixt the now discarded bicycle-wheel and the new "Twisted-Strip Voltmeter," in this and almost every other respect. It is really impossible to conceive of anything more simple as a means of accurate measurement than this beautiful instrument. At first sight the twisted strip looks like an Ayrton and Perry magnifying spring, such as they have employed in so many recent applications (including the bicycle-wheel voltmeter itself), but in reality it is an even simpler affair. A strip of metal—preferably platinum-silver—is fixed at each end, and made red hot, then seized in the middle by a pair of pincers, and twisted round until it attains a permanent set. The

Digitized by Google

twist on either side of the centre is of course in opposite directions. Such a strip possesses the property that when subjected to a moderate longitudinal strain its centre rotates, whilst its extension is very slight. The voltmeter consists, therefore, of such a strip carrying at its middle point a suitable index and subjected to a permanent longitudinal stress which has been just sufficient to give the pointer one complete rotation. If, therefore, a current be sent through the wire, the expansion due to the rise of temperature relieves the strain and permits the pointer to rotate through a certain number of degrees. We need not add anything more to show the wonderful simplicity and practicability of the apparatus. Its delicacy is also equally remarkable. As for the range, we believe that Prof. PERRY has not at present gone beyond 50 volts in a direct-reading instrument; for alternating currents a suitable transformer is easily provided. For a reduction as great as from 2,000 to 50 volts a transformer of quite small dimensions serves the purpose. Another highly interesting method by which the range may be extended is by the use of a twisted strip made of *carbon*. Messrs. WOODHOUSE and RAWSON have supplied Prof. PERRY with some twisted carbon strips of marvellous delicacy and, of course, of much higher resistance than the platinum silver. We see no reason to doubt that in this voltmeter the electrical world will find an instrument admirably adapted both for laboratory and for commercial purposes. It ought also to be conspicuously inexpensive.

IN the Paper by Mr. W. H. PREECE "On the Relative Effects of Steady and of Alternate Currents on Different Conductors" we have the record of an extensive and careful series of experiments directed to a definite practical end. We have all learnt a great deal within the last eighteen months with regard to the tendency towards a peripheral distribution of alternating currents in conductors. The extent to which this phenomenon occurs depends upon the frequency of the alternations, and upon the diameter and material of the wire. Mr. PREECE sought to determine by direct experiment whether the effect was perceptible under the ordinary conditions of alternate-current working. The answer is—as regards copper conductors of such sizes as are used in practice, and with periods ranging from 60 to 107—that no increased loss of energy due to the effect in question is observable. Mr. MORDEY has, we believe, also arrived experimentally at a similar result. It is, however, to be regretted that Mr. PREECE was not able to increase his frequencies or to maintain the same mean current density in wires of larger diameter until the practical limit of the effect was arrived at. We are pleased to learn that the experiments are to be continued, and it is to be hoped that arrangements will be made permitting such observations to be undertaken. In iron wire, owing to circular magnetisation, the limit is, of course, arrived at much earlier. The effects become somewhat complex, and, as Dr. LODGE has shown, when pushed to the limit with high frequencies some very paradoxical results ensue. We must not, however, be tempted to enter upon this side of the subject at the present moment.

THE last of the Practical Papers in Section A was one by Prof. SILVANUS THOMPSON, "On Sparkless Electro-Magnets." The practical upshot of Prof. THOMPSON'S research amounts to this, that the most effective means for the prevention of sparking on opening a circuit containing the coils of an electro-magnet is to surround the core of the magnet with a substantial shield of copper. Of course, there are many cases which arise in practice where this would be impossible. We could not, for instance, adopt it in any case with alternating currents, but, fortunately, as is now pretty generally known, under similar conditions of E.M.F. and current density the alternating-current spark is a very much feebler affair than the continuous-current one. Again, the device does not admit of use in armatures; but we are inclined, notwithstanding, to believe that it would be well worth while to adopt this precaution for the field-magnets of series-wound high-tension dynamos. We believe that certain makers already do this, at least in certain cases.

TURNING now to Section G, we have referred to the Papers of Mr. SWINBURNE and of Major-General WEBBER in another column. Mr. MANVILLE gave a lucid account of the work carried out at Northfleet, where an electric tramway on the series-system has now been in quite successful operation for about five months. The detailed arrangements were fully described and illustrated in *The Electrician* of March 15th. When this line was first constructed some feeling of anxiety was naturally experienced, at least by those not connected with the work, as to the probability of the successful operation of the "spring-jacks," but after the experience of five months, in which it has not been found necessary to make any alterations in the original design, we think it may be reasonably believed that the method is a thoroughly practical one. We hope shortly to lay before our readers an account of a remarkable, and perhaps somewhat unexpected, development of series electric traction. With regard to Mr. WEBSTER'S Paper on "The Electrical Purification of Sewage," it is highly satisfactory to know that the large-scale experiment which is now being tried at Erith continues to give such excellent results. The question resolves itself into one of cost pure and simple, for it has been shown that any required degree of purity can be obtained in the effluent if the expense be not considered.

IT was interesting to learn from Mr. PREECE that the question of Telephonic communication between London and Paris is being seriously considered. As to the possibility of effecting the communication there can be no question—whether it will pay is another matter. Mr. KILLINGWORTH HEDGES described an ingenious form of safety-valve for use with transformers, which we described at the time when it was shown at a recent Royal Society *soirée*. Finally, Prof. FORBES gave a very favourable account of his experience with an electric launch which he hired from Messrs. IMMISCH whilst staying on the river near Maidenhead.

THE Committee of Section A has decided to adopt *en bloc* (with an exception to be mentioned) the decisions of the recent

Digitized by Google

International Congress as regards nomenclature. Instead of the term *resistance fictive*, defined as the ratio of the "effective" E.M.F. to the "effective" current, they have adopted the term "impedance," defined by the well-known formula which expresses the "apparent resistance" in terms of L, R and *n*, *when the current wave is sinusoidal.* We think that this definition will meet with general approval. The authorisation of the term is the more satisfactory to ourselves since it was first proposed in these columns by Mr. OLIVER HEAVISIDE, and was consistently employed by us long before it came into common use.

WHEN Mr. PREECE, in Section G, hazarded the observation that it was the most difficult thing in the world—or words to that effect—to kill a man by electricity, it was certainly understood by those present as a mere *obiter dictum*, and not as a scientifically-accurate statement. Probably no one has been more surprised than Mr. PREECE to see this remark put forward in the London and the New York papers as his deliberate opinion, or to find in yesterday's *Times* that it has resulted in a challenge from a Brighton doctor to "lay hold of a 2,000 volt electric wire." The fact is, as every electrician knows, that a deadly shock can, if necessary, be administered with fatal facility. The problem, which has been discussed in New York with such a strange degree of gusto and so much bad taste, is somewhat different. It was made a *sine quâ non* to kill without disfiguring, and to this end it was proposed to resort to wet sponge electrodes and similar methods. We shall be thankful to hear the last of this unpleasant business, but we cannot deny that electricity can destroy life.

THE sudden change of front of the Exeter Town Council with regard to overhead wires argues at the best but little foresight on the part of that body. The permission granted in June to the Exeter Electric Light Company to run its cables overhead is now—if a large number of the Corporation succeed in having their way—to be withdrawn on no better grounds than that here and there the wires run too close to the houses, and that the standards are "sadly disfiguring." An underground system is doubtless an advantage from an æsthetic, if from no other point of view, but in a town like Exeter, where the demand for current will probably be comparatively small for some little time, it seems somewhat unreasonable to expect such an expensive luxury at once. The Corporation presumably gave its consent with its eyes open to the fact that electric light wires were not exempt from the action of gravity, but required supports, and it was moreover provided with a plan showing the proposed positions of the posts; so that to withdraw its permission now that the company has expended a large sum of money would be, so far as we can see, utterly inexcusable. As to the dangerous proximity of the wires to the houses, we have no doubt the company would be perfectly willing to make any feasible alteration.

As will be seen elsewhere, the Paddington Vestry are about to consider yet another report on the subject of electric lighting. The first report submitted to this body was, it will be remembered, that of Mr. S. J. MACKIE (*Electrician*, December 21, 1888), who in September last worked out a 37 or 50 per cent. profit to the Vestry from its proposed central station on the basis of a total annual output of 3,186 hours under full load. At the beginning of April a second and carefully-considered report (*Electrician*, April 12, 1889) was sent in by Prof. GEORGE FORBES, and now the Electric Lighting Committee, after lengthy deliberations, have issued their report, making the third within twelve months. The Committee recommend that the work should be entrusted to some well-established company, which, in view of future purchase, is to have its station and mains entirely within the parish. The system preferred by the Committee is that of storage-batteries and sub-stations.

A CORRESPONDENT writes as follows:—"I was with a friend at the Birmingham Exhibition endeavouring to fathom the mysteries of WOOLRICH'S historical plating machine, which, it may be admitted—without any slur upon the venerable machine or its inventor—might, by the uninitiated, be mistaken for anything, when we became conscious of an unprotected spinster of tender (?) age and anxious countenance hovering around us. Said the unprotected one, on catching our attention, 'Oh, if you please, will you weigh me?' The mistaken one was directed a few stalls lower down to where the delicate operation could be performed with the aid of the incompressible fluid which has just been dislodged from its ethereal entanglement."

Bradford.—The municipal central lighting station will be inaugurated at noon to-day by the mayor.

Innsbruck.—The municipal central lighting station erected by the firm of Ganz and Co. is now completed.

The Electric Light on the River Steamers.—The Victoria Steamboat Association are lighting some of their steamers by electricity.

Interruption of the Tangier-Gibraltar Cable.—Telegraphic communication between Tangier and Gibraltar is interrupted, the cable across the Straits having broken down.

Altona.—The Zoological Gardens of this town are now lighted at night by 30 arcs and a large number of incandescents. The work was undertaken by Messrs. Heirwicke and Goos.

Indian Telegraph Service.—It is probable, says *Indian Engineering*, that Colonel Mallock, Director-General of Telegraphs in India, will be allowed a year's extension of office.

Dewsbury.—At a meeting of the Dewsbury Town Council last week it was decided to oppose all applications which may be made by electric lighting companies for supplying the borough with electric light.

Newcastle.—Final approval has been given by the Newcastle Town Council to the licenses of the Newcastle and District Electric Lighting Company and the Newcastle-upon-Tyne Electric Supply Company.

Airdrie.—At a recent meeting of the Airdrie Council it was resolved to proceed with the necessary advertisement of the Council's intention to apply for a Provisional Order in regard to the electric lighting of the town.

Brunnen.—The village of Brunnen, on the Lake of Lucerne, is lit by electricity, the motive power being obtained from the turbines at the spinning mill of M. Shach, where over 200 horse-power is available for electric lighting purposes.

Burslem.—The Town Clerk has been instructed to write to the Midland House-to-House Electricity Company and the Municipal Electric Light and Power Corporation, informing them that the Town Council will not consent to their applications for Provisional Orders.

Digitized by Google

Lectures on Dynamo Machines.—Mr. W. B. Esson will deliver a series of twelve lectures on dynamos at the Hanover-square School of Electrical Engineering on Wednesday evenings, commencing on October 16th. Further particulars will be found in our advertisement columns.

Personal.—We are informed that Mr. Parsons, who had the management of the Sunbeam Company's Lamp Works at the time when the Super-incandescent—afterwards called the Sunbeam Lamp—was initiated and perfected, has resigned all connection with the Sunbeam Lamp Company.

Worcester.—At the Watch Committee meeting on Friday last, the Town Clerk pointed out that several companies had given notice to apply for Provisional Orders authorising them to supply electricity to the city, and it was eventually resolved not to recommend the Corporation to move in the matter.

Southport.—The Gas Committee of the Southport Corporation have resolved that an intimation be given to all parties who have given notice of their intention to apply for Provisional Orders to supply electricity within the borough, that the Corporation intend to withhold their consent to such applications.

The Edinburgh Exhibition.—At a meeting of the Executive Council of the Edinburgh Electrical Exhibition, held on Thursday last week, a letter was read from the Marquis of Lothian, K.T., accepting office as President of the Exhibition. The Dundee Town Council have contributed £200 towards the guarantee fund.

Glasgow University.—It is officially announced that the Queen has been pleased, on the recommendation of the Secretary for Scotland, to appoint Prof. Archibald Bart, of the Yorkshire College, Leeds, to be Professor of Civil Engineering and Mechanics in the University of Glasgow, in the room of Prof. Thomson, resigned.

Sheffield.—The Improvement Committee of Sheffield has recommended the Council not to give its consent to any license or Provisional Order being granted to the Sheffield Telephone Exchange and Electric Lighting Company, on the ground that the Council may probably itself seek to obtain powers necessary for electric lighting.

San Sebastian.—The plant at the central lighting station of the San Sebastian Gas Company comprises a multitubular Collet boiler, a 65 horse-power Corliss engine, and two Oerlikon dynamos giving 200 amperes and 130 volts. The charges are 2fr. 50c. per arc lamp per hour, and 6c. per 16 candle-power incandescent lamp per hour.

Chester.—A special meeting of the Town Council was held on Wednesday for the purpose of considering the desirability of making application for a Provisional Order under the Electric Lighting Acts. A resolution to the effect that powers should be applied for was carried unanimously, and it was decided to refer the matter to the Watch Committee.

Finsbury Technical College.—The evening classes at this institution comprise special lectures on hydraulic machinery by Prof. Perry, lectures and instruction in drawing-office work, together with courses for apprentices and others in mechanical and electrical engineering, technical chemistry, etc. For further particulars see our advertisement columns.

Leamington.—As things stand at present, the contract with Messrs. A. Chamberlain and G. Hookham for the supply of electricity to the Parade lamps terminates at Christmas. Several members of the Corporation are, however, in favour of negotiating with Messrs. Chamberlain and Hookham with a view to improving the present system of lighting the Parade by electricity.

The City of London College.—We have received from the City of London College, Moorfields, E.C., a copy of the syllabus of lectures for the ensuing session. Classes are devoted to Civil and Mechanical Engineering, Surveying, and Technical Drawing. The engineering department is under the care of Prof. Henry Adams, M.I.C.E. The Michaelmas term commences on Monday, September 30th.

Falmouth.—At a recent meeting of this body the following resolution was moved :—"That the time has arrived when this authority should apply for an Act of Parliament for powers to supply Falmouth with electric light, and that the parish Local Board, the Penwerris Lighting Committee, and the Corporation of Penryn be asked to join in the scheme." The matter was referred to the Lighting Committee.

Goulburn (New South Wales).—Tenders are to be called for lighting the streets and parks of Goulburn by electricity, with or without the right of supplying private persons with light for commercial or domestic purposes, but without the exclusive right of supplying labour and fittings for carrying the light into private properties. Two systems will be provided for in the specifications, so that the town will have the choice of either.

The Edison-Swan Company.—In the *Financial News* of yesterday a correspondent writes as follows :—"If 474 central electric lighting stations are promised to us (vide *The Electrician* of 13th inst.), and the average number of lamps lit by each station be 10,000, what will be the dividend paid by the above monopolists when the promise is fulfilled? I estimate that with lamps at their present price it should be something like 200 per cent."

The Electro-Harmonic Society.—The concerts of the Electro-Harmonic Society this season will be six in number, and will take place on the evenings of the following dates :—September 27th, smoking concert; November 1st, smoking concert; November 29th, ladies' night; January 31st, 1890, smoking concert; February 28th, ladies' night; March 28th, smoking concert. In arranging the programme for the concert on February 28th it is proposed to rely mainly on musical amateurs.

Mr. Edison in Berlin.—Mr. Edison arrived in Berlin on Thursday last week. On Friday he visited the Accident Prevention Exhibit. On Saturday morning he visited Charlottenburg, and viewed the works of Messrs. Siemens. He returned to Berlin on the "Electra," a boat fitted with electric motors. In the evening Herr Werner Siemens gave a grand dinner in his honour at Charlottenburg. On Monday Mr. Edison and Herr Siemens left for Heidelberg to attend the Congress of German Naturalists.

The Glasgow Technical College.—We have received the syllabus of engineering classes at this college for the Session 1889-90. We observe that Prof. Jamieson conducts a day workshop and two years' laboratory course for those who have not entered upon an apprenticeship, or who can leave their works during the winter months, as well as evening lectures for those who are employed in engineering establishments. The aim of these courses is to provide a sound practical knowledge of electrical testing, as well as of steam engines, gas engines, boilers and dynamos.

Arbroath.—At meetings of Arbroath Police Commissioners and Gas Corporation held on Monday it was unanimously agreed to refuse consent to the Scottish House-to-House Electricity Company to apply for a Provisional Order. It was further agreed to oppose the application if made, and to request the Board of Trade to give the local authorities time to consider the needs and desires of the community, and the desirability of the Gas Corporation itself applying for a Provisional Order authorising the Corporation to supply electricity within the limits of their Act of Parliament if such should be required in the locality.

Dundee.—At a special meeting of the Gas Corporation, held on Monday, the Corporation unanimously refused to give their consent to the proposed Provisional Order of the Scottish House-to-House Electricity Company, and resolved to oppose the application if made, and to request the Board of Trade to give to the Local Authority time to consider the needs and desires of the community, and the desirability of applying for a Provisional Order authorising them to supply electricity within the bounds of their jurisdiction. At a subsequent meeting of the Police Commissioners similar resolutions were likewise put and unanimously carried.

Great Yarmouth.—The Town Council at their last meeting received a report from a Special Committee, which stated that they had considered the report of the borough surveyor on the supply of the electric light throughout the borough, and that they had instructed him to prepare a further report showing

Digitized by Google

the cost of an installation sufficient to light the public streets and roads in the borough. They recommended the Council that it was expedient to prevent any company from getting the electric lighting of the town into its hands, and to oppose the granting of the Provisional Orders now applied for by two companies. This report was adopted.

Exeter.—At the meeting of the Town Council on Wednesday last week the town clerk and the surveyor were plied with numerous questions with regard to the proceedings of the Electric Light Company. It was asserted that the overhead wires were being run far too close to the houses, and the posts were condemned as "sadly disfiguring." Finally a resolution directing the town clerk to make inquiries as to the regulations of the Board of Trade was carried, and notice was given that at the next meeting a resolution would be moved that the permission given to the Electric Lighting Company to erect posts and wires in the streets be determined at the earliest possible date.

Bristol.—The Electrical Committee, at their meeting on Wednesday last week, resolved to request Mr. Preece to prepare specifications to enable the Corporation to advertise for tenders for the supply of electric light by one of the systems of which they might approve. Mr. Preece, it will be remembered, stated in his report that in his opinion the proper system to introduce into Bristol was the alternate-current transformer system. He estimated that the Corporation ought to be prepared ultimately to supply 70,000 lamps, and that this would mean eventually a capital of £300,000. A commencement, he thought, might be made with a capital of £30,000 and a plant for 5,000 lamps.

Hove.—A special meeting of the Hove Commissioners was held on Thursday last week to take into consideration the expediency of applying for a Provisional Order under the Electric Lighting Acts, 1882 and 1888, to authorise the supply of electricity by the Commissioners for public and private purposes within the town of Hove. Mr. Woodruff, in moving that the Town Clerk be instructed to apply for a Provisional Order, reminded the members of the inquiry held recently in Brighton, and said that owing to what was said at that inquiry they were virtually pledged to do something in the matter. The electric light, he thought, was now within a measurable distance of being made financially a success. They incurred obligations by taking this Order. One of them bound them to supply a certain amount of lighting within two years of the granting of the Order, but they were probably not liable to any other penalty in the event of non-compliance but the revoking of the Order. He was not prepared to say that he should support a proposal that the Commissioners should undertake the electric lighting themselves. If they obtained the Order they might be able to hand it over to a good company upon terms which it would be to the interest of the ratepayers to accept. The motion was carried.

Uranium.—Exactly a century ago—namely, in 1789—Klaproth succeeded in isolating from a dark-coloured mineral known as pitch-blende a yellow oxide, which, after carefully testing, he pronounced to be the oxide of a new metal. To this metallic substance he gave the name of uranium, so calling it after the planet Uranus, then recently discovered by Herschel, and it was at once classed among the rare metals, and still remains so. Its rarity is indicated by its market price, which is about £2,400 per ton. Uranium is found in Cornwall, Saxony, and Bohemia; but up to the present time it has only been met with in isolated pockets and patches. The centenary of its discovery by Klaproth has, however, been marked by the finding of a continuous lode at the Union Mine, Cornwall. This discovery is regarded as unique in the history of the metal, for the lode is what is known as a true fissure vein, and the ore is found to contain an average of 12 per cent. of the pure metal, the assays going up as high as 30 per cent. in some parts of the lode. It is anticipated that the present discovery will enable several important applications of the metal to be followed up. Uranium may, for instance, be used as a substitute for gold in electroplated ware, inasmuch as with platinum and copper it forms two beautiful alloys, each having the appearance of gold, and the former also resisting the action of acids.

A Trip in the Electric Launch "Eta."—The following account of a trip to Oxford and back in Messrs. Immisch and Co.'s electric launch "Eta" may prove of interest. The launch, with three passengers on board, started from Hampton on Saturday, the 7th, and Maidenhead, 26 miles, the first stopping-place, was reached in about four hours. Here the cells were recharged during the evening at the charging station. On Monday morning the journey was renewed by a run to Goring, 34 miles, where the cells were again recharged during the night. At ten o'clock on Tuesday morning Goring was left behind, and, after two halts on the stream, Oxford was reached by four o'clock in the afternoon. During the two hours the "Eta" lay at Oxford she was an object of considerable attraction, being the first electric launch that has been above Goring. Leaving Oxford at 6 p.m., a stop was made at Abingdon for the night, Goring being reached by noon on Wednesday. A small charge was put in during lunch, after which the journey was resumed to Reading, which was left on Thursday morning at eight o'clock, and a short stay being made at Henley, Maidenhead, the end of the journey, was reached at 1 p.m. It will be noticed that the sixty miles from Goring to Oxford and back was accomplished with but one charge. The "Eta" has therefore made two records, one for distance and another for work.

The Rating of Machinery.—An important and largely attended meeting of manufacturers from all parts of England was held on Wednesday last week, at Bristol, to consider the attempts which have been made to assess all kinds of machinery to the local rates, and to consult as to the steps which should be taken to protect the interests of all those affected. It was unanimously resolved that a National society for the exemption of machinery from rating be formed among the machinery users of the kingdom, for the purpose of assisting manufacturers to resist illegal and excessive assessments. It was also resolved to prosecute an appeal to the Superior Courts against the recent decisions of the Somersetshire Quarter Sessions in respect of the machinery in the mills in the Chard Union, and to promote a Bill in Parliament which shall declare the law and render it free from any doubt on the subject. Mr. Humphreys Davies, F.S.I., rating surveyor of the Adelphi, London, was appointed secretary, and arrangements were made for a thorough organisation of the affected interests throughout the country. Subscriptions were paid or promised amounting to upwards of £2,000. The feeling of all those present was expressed strongly that the question was of great national importance, and that to rate machinery would be to place our manufacturers at a serious disadvantage in competing with foreign countries, as it would largely increase the cost of production.

Paddington.—On Tuesday the report of the Electric Lighting Committee of the Paddington Vestry as to the action to be taken by that body for the supply of electricity for lighting purposes in Paddington was issued. The report states that in the opinion of the Committee there seems little doubt that arc lamps are best for street lighting. The cost, the report goes on to say, is, however, difficult to arrive at owing to the great difference of opinion among experts as to the number required for effective lighting. Taking everything into consideration, the Committee think it advisable for the Vestry to entrust the work of electric lighting to a well-established company: and in view of the possibility of the local authority desiring to purchase at any future time the undertaking of any company in the parish, the Committee considered that it should be a *sine qua non* that the central stations for the production and supply of electricity should be constructed, and the distributing mains laid, so as to form a complete installation for Paddington, independent of all communication with other parishes. The Committee think the continuous-current system, in conjunction with storage batteries as supplied by the Chelsea company, preferable for electric lighting. Mr. Slater, electrical engineer, in his report to the Committee, urged that the Vestry should undertake the public and private lighting of the parish. He said that the parish, being, perhaps, the wealthiest in London, ought to be the best-paying place for electric lighting. In such a populous parish he believed that electricity could be supplied to private consumers at a rate equal to 4d. to 5d. per Board of Trade unit. A special meeting of the Vestry is to be held to consider the Committee's report.

BROOKS' UNDERGROUND SYSTEM.

On Monday last we witnessed some experiments with the above system of underground mains with oil insulation at the works of Messrs. Johnson and Phillips, Charlton, Kent.

The conductor experimented upon consisted of seven No. 18 B.W.G. wires, each covered with textile matter to a diameter equal to No. 12 B.W.G., made up into cable and braided lightly over all. This conductor was 140 yards long, and was drawn into 1in. iron gas tubes, which had been laid for the purpose in Messrs. Johnson and Phillips' premises. In order that the conditions of the test might approximate as nearly as possible to those of ordinary working, the conductors were spliced at two points, splice boxes being provided in the tubes for this purpose. The object of the test was to show with what economy a good insulation may be obtained. The galvanometer employed to make the measurement had a resistance of 12,500 ohms, and when shunted with 10 ohms a deflection of 37deg. was obtained through 1·24 megohms. The battery employed consisted of 200 Leclanché cells.

Experiment 1.—One pole of battery was earthed and the other connected through galvanometer to one of the seven wires, the remaining six wires having their ends clear. After one minute's electrification the deflection of galvanometer was 15deg., showing the insulation to be $\frac{37}{15} \times \frac{12,500+10}{10} \times 1 \cdot 24 = 3,830$ megohms, or $\frac{140}{1,760} \times 3,830 = 306$ megohms per mile. Another wire was substituted for the first with the same result.

Experiment 2.—The same as the above, except that the remaining six wires were earthed. Three different wires were tested, giving respectively 240, 266, and 240 megohms per mile, or an average of 249 megohms per mile.

Experiment 3.—The whole of the seven wires were connected together at one end, and the aggregate insulation measured, the result showing an insulation resistance of 88 megohms per mile. In this experiment the conditions obviously approached more nearly those which would obtain in an electric light cable than in experiments 1 and 2. It will be noted that the last result would indicate a considerably higher value for each wire than that obtained when the wires were measured separately. This is always found to be the case with Mr. Brooks' system, and is, we think, accounted for by the fact that when tested singly leakage takes place from the whole surface of the wire, whilst when the seven wires are bunched probably no sensible leakage can take place from the inside wire or from the inwardly directed surfaces of the outside wires.

Experiment 4.—A 100-volt Kapp alternating dynamo was connected to a transformer, by means of which the E.M.F. was raised to 1,000 volts, as shown by running ten 100-volt Swan incandescence lamps in series across the terminals. Two of the seven wires were connected to the opposite lamp terminals, so that the insulation was subjected to an alternating E.M.F. of 1,000 volts. The results showed that the insulation could not be sparked through with this E.M.F.

Experiment 5.—Two pieces of $\frac{7}{18}$in. cable, with a thin covering of textile matter, had been twisted together, the ends being kept apart. The twisted ends were immersed in a bucket nearly filled with Mr. Brooks' oil compound, and the other ends brought up through two glass tubes. In this case more resin than usual had been put into the mixture in order to make it more manageable for the experiment. The terminals of a large induction coil by Messrs. Apps were now connected to the two ends of the cable, and after several unsuccessful attempts to prevent the discharge from leaping to the sides of the pail, during which several thicknesses of $\frac{1}{16}$in. sheet rubber were pierced, a nearly continuous stream of sparks, 7½in. long, was obtained between two bared places on the connecting wires. Thus, according to Mr. De la Rue's tables, an E.M.F. of something like 170,000 volts was withstood by the insulation between the twisted wires. After being subjected to this strain, a test with the galvanometer gave no readable result. Mr. Brooks states that he has subjected a similar arrangement to the above, but with several inches of water upon the top of the oil, to a test of one year's duration, the wires having been connected across the terminals of a 1,000-volt Brush circuit. No change of any kind had taken place at the end of this time, the insulation remaining as perfect as at first.

A specimen of cable was exhibited consisting of 510 No. 16 B.W.G. wires, each having only a very thin covering, there being less than $\frac{1}{32}$in. between the wires. The cable measures only 2½in. diameter over all, and is now in use in telephonic work. Upon completion 10 wires were found to be broken or faulty, leaving 500 good wires. The insulation of the separate wires in this cable varies from 6 to 14 megohms per mile, and it is a curious fact that the wires having the lower insulation were found to "talk" better than those with the higher. The lower ones have consequently been selected for connection with some long-distance lines.

Mr. Brooks states that he is able to draw 1,000ft. of his cable into a pipe without intermediate hand-holes; thus by drawing from the centre both ways a length of 2,000ft. can be drawn in.

A VISIT TO THE INSTITUTE OF MEDICAL ELECTRICITY.

In response to an invitation from the Directors of the Institute of Medical Electricity (Limited), we recently visited their central establishment at 24A, Regent-street, and found much to interest us.

After an introductory visit to the office and consulting room we were shown a large and cheerful-looking room, designated the men's room, in which, upon the wall, are fixed switch-boards arranged with suitable connections for supplying all the forms of current used in ordinary cases. One of these switch-boards is shown in Fig. 1.

Upon an ordinary table lay electrodes, pad, plate, and handle, of numerous shapes and sizes, together with flexible and well-insulated rheophores for connecting the electrodes to the switch-board, so that everything necessary for ordinary applications was ready to hand. In a cabinet near a strong reserve of similar electrodes was arranged, together with electrodes for electrolysis, dilatation, cautery, and other surgical purposes.

In one part of this room stands an ingenious apparatus for carrying out the electro gymnastic system (Lawrence's patent) whereby electric currents of suitable character and strength are passed through the limbs or whole body of patients during mechanical exercise, either passive or active. We give in Fig. 2 a sketch of the apparatus, the mechanical part of which is known as Chadborn and Coldwell's "Excelsior" gymnasium.

It is claimed that by means of this system weak or injured, and even paralysed limbs may, as long as their vitality is not entirely destroyed, be rapidly restored, and that the process is simple, natural and pleasant. For the treatment of spine curvatures, round shoulders, &c., and certain digestive troubles this system is also likely to prove beneficial. We were informed that the apparatus shown is only one of many forms in which the system will be applied, and that there is now in hand a form for the special treatment of writer's cramp.

In the ladies' room there is another switch-board similar to that shown in Fig. 1, and here we were shown some special electrodes designed by Dr. Arthur Harries, physician to the Institute, for the treatment of certain skin diseases by electrolysis. Some of these electrodes we illustrate in Fig. 3. We understand that this form of treatment is a new departure introduced by Dr. Harries, and promises to give good results.

The electrified room which we next visited is fitted in such a manner (Byng's patent) that the air-space between floor and ceiling is converted into an electric field by the use of alternating-currents of high potential. A slightly elevated platform stands upon glass insulators and covers all the floor of the room with the exception of a margin round of about 18in. This platform is covered with sheet lead, and is connected by well insulated wire to one pole of the secondary wire of a powerful induction coil. Above this platform, or floor, is placed an insulated

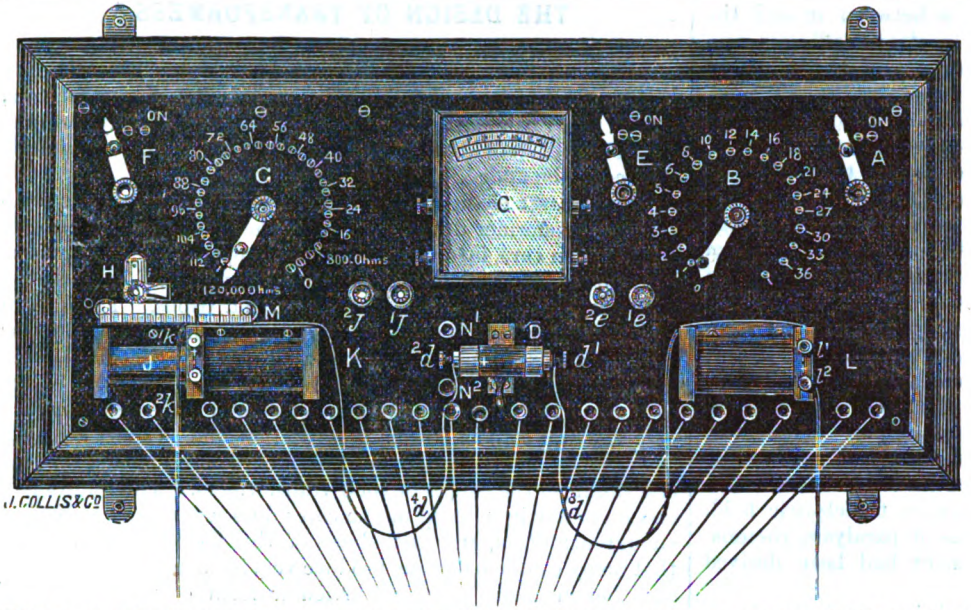

FIG. 1.—A, switch for the continuous-current circuit; B, dial collector for controlling no. of cells in circuit; C, galvano meter, graduated in milliamperes, and always kept in circuit with the patient when continuous current is administered; D, current reverser—a^1 and d^2, terminals of the continuous-current circuit, d^3 and d^4, flexible rheophores; E, switch of a separate circuit for lighting a small incandescent lamp used to examine cavities—e^1 and e^2, terminals of the lamp circuit; F, switch for the induction coil circuit; G, rheostat of 12,000 ohms in the primary circuit of the coil; H, contact breaker; J, primary coil—j^1 and j^2, terminals of primary coil; K, 10-ohmsecondary coil—k^1 and k^2, terminals of secondary coil; L, 2,000-ohm secondary coil interchangeable with K—l^1 and l^2, terminals of 2,000-ohm coil; M, scale graduated in millimetres showing the distance the coils K or L are passed over coil J; N^1 and N^2, terminals for connecting any of the coil terminals with d^1 and d^2 so that currents from both sides of the board may be drawn simultaneously.

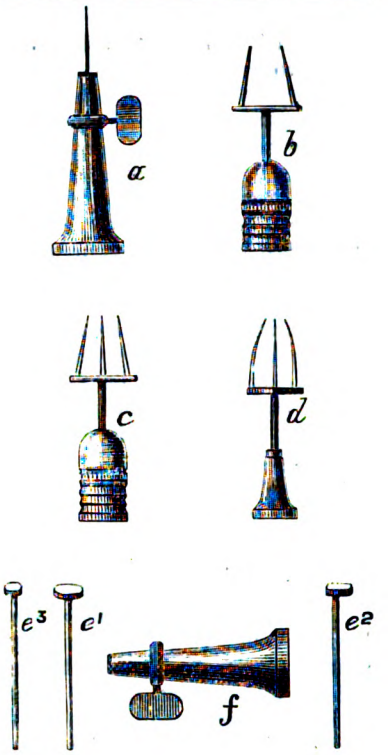

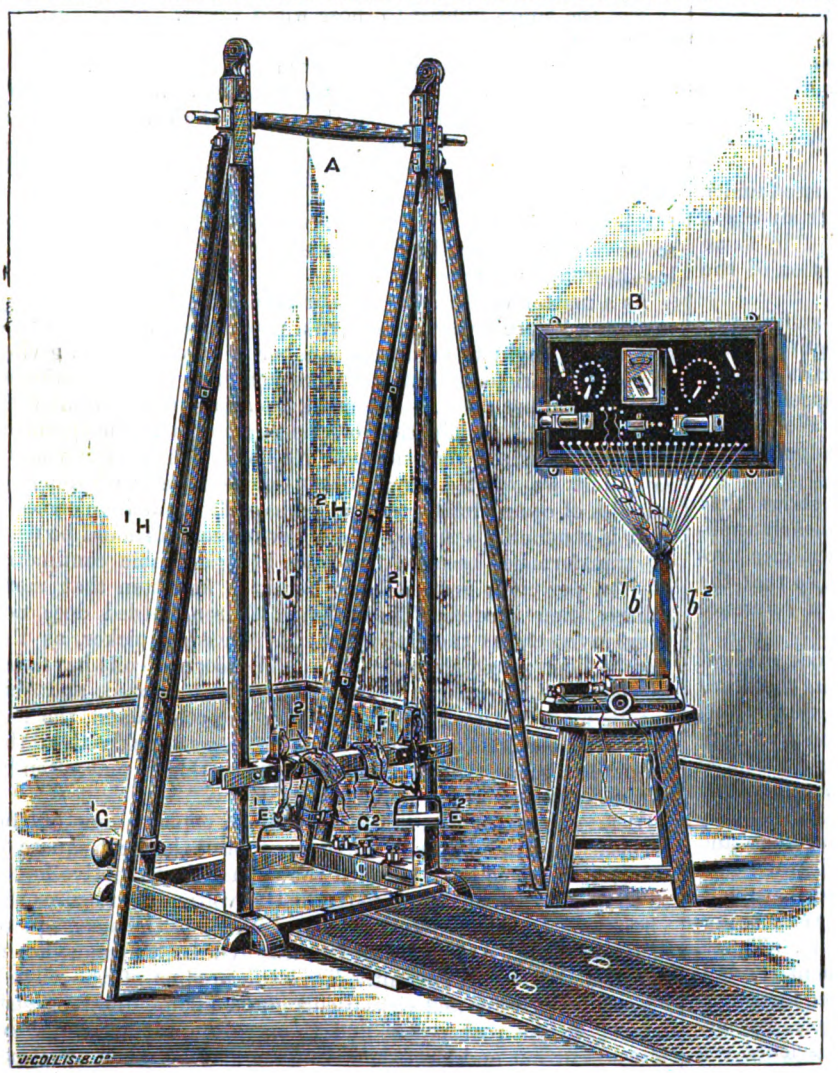

FIG. 2.

A, machine for mechanical exercise; B, general switchboard similar to that shown in Fig. 1—b^1 and b^2, conducting wires running under the floor to C; C, switch arrangement by variations in which the current may be passed at will through the whole or different portions of the patient's body; D^1 and D^2, insulated stand electrodes of fine wire gauze for conducting the current to or from the patient's foot or feet during exercise; E^1 and E^2, handle electrodes for conducting the current to or from the patient's hand or hands; F^1 and F^2, bandage electrodes for conducting the current to the arms or legs; G^1 and G^2, spring sliding contacts to which adjustable weights are attached; H^1 and H^2, conducting rods; J^1 and J^2, conducting flexible cords; K rheometer for measuring the resistance of patients by means of alternating currents and a telephone.

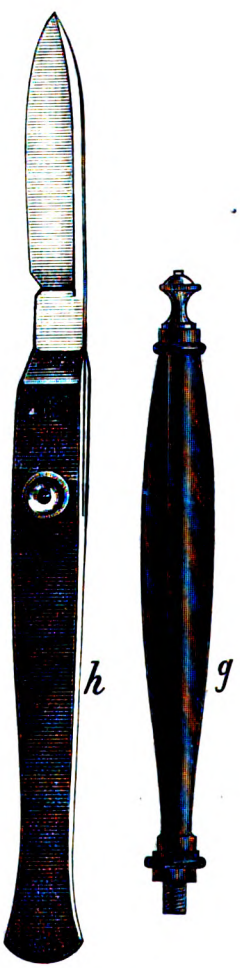

FIG. 3

a, needle used for the removal of hair; *b* and *c*, bipartite and tripartite instruments used in the simultaneous electrolisation of several points in a nodule; *d*, tripod arrangement used in the treatment of discrete nodules of lupus or scrofuloderma; e^1, e^2, e^3, three irregular-headed electrodes specially shaped to meet the requirements of a recent case of superficial nævoid developments; *f*, a base suitable for holding the electrodes shown in e^1, e^2, e^3; *g*, light insulated holder; *h*, ordinary surgical knife capable of electrical connection at its base, used, amongst other things in the treatment of enlarged facial or other veins

Digitized by Google

ceiling of light brass work, the distance between it and the insulated floor being adjustable. This insulated ceiling is connected to the other pole of the secondary wire of the induction coil.

When the apparatus is in action a patient standing, sitting, or lying in the "field" becomes electrically influenced without experiencing any shock, or (in most cases) any of the sensations usually accompanying electrical action on the body; but if any two points on the body be connected to a telephone the passage of alternating currents is distinctly audible. The tonic effect of a short stay in the electric field is considerable, but the form of treatment most practised in this room is known as electro-manipulation, introduced by Mr. Lawrence, which consists of the manipulation of the patients' limbs or body, as in massage, while the patient is in the "field," and the manipulator is connected to "earth." Thus high potential alternating currents are concentrated under the hands of the manipulator where most needed, without any unpleasant sensation on the part of the patient, while at the same time the general tonic effect is obtained by reason of the patient's presence in the electric field. We were shown particulars of some cases of paralysis, rheumatism, anæmia, &c., in which marked benefit had been derived from this form of treatment.

The bath-room contains a large, well insulated oak bath, having connections conveniently arranged round it, with a switch-board somewhat similar to those already mentioned, but with a larger induction coil. Sponge, plate and bar electrodes of various sizes are used for the different forms of electric bath here administered, and all are ready to hand.

The experiment room contains several valuable pieces of electrical apparatus, and we examined some of the notes of experimental investigations in which, with the colaboration of several medical men and students, Dr. Harries and Mr. Lawrence are engaged. These researches will, we think, when completed, throw light on many points in electro-physiology and therapeutics at present obscure.

Here we also saw the first ozonised cabinet, constructed under a recent patent, in which it is proposed to treat certain chest diseases by strongly (electrically) ozonised air, aided in some cases by exercise to deepen respiration. Our description of the cabinet must be deferred for the present.

The battery rooms require no special comment—suffice it to say that all the electrical power used (with the exception of one Wimshurst influence machine) is, at present, obtained from primary batteries, and these are mostly Coxeter's special form of Léclanché. The electrified room was fitted by Woodhouse and Rawson (Limited), most of the other apparatus being supplied by Coxeter and Son.

A glance at the Treatment Book in the office shows that careful record is kept of all cases, for in it is entered each application administered, and the details in proper electrical measurements of E.M.F., current strength and resistance, so that the record can hardly fail to prove a valuable work of reference and of scientific interest.

We were also shown a prescription form on which medical men are invited to prescribe *in proper electrical terms* the doses of electricity they wish their patients to receive. Surely this is evidence of an advance in medical electricity, and we congratulate the directors of the Institute in having introduced such a form and in having found medical men able and willing to use it.

In the course of a pleasant chat with the courteous and energetic manager, Mr. H. Newman Lawrence, we learned that the work of the Institute is steadily increasing, and that medical men are giving, almost daily, fresh evidence of their appreciation of the opportunities and advantages it offers. This is as it should be, for here we find no electrical treatment is administered without medical sanction, and no sensational assertions regarding the marvellous curative powers of electricity are made; all is plain sober fact, as far as modern science can make it so. High-class instruments, skilled attendants, accurate measurements and careful records. We can hardly imagine an establishment better fitted for the difficult and unique work the directors have set themselves, nor managed in a manner more worthy the support of medical and scientific men, not to mention the public generally.

THE DESIGN OF TRANSFORMERS.*

BY JAS. SWINBURNE.

So much has been already said on the design of transformers, and so many calculations have been made and so many formulæ given, that it would seem at first sight as if there was little that could be added.

The greatest change that has taken place recently in the practice of transformer design has been the substitution of a continuous iron core, interlinked with the copper coils, for a straight core with wires wound on it, as in the Ruhmkorff coil and the secondary generators of MM. Gaulard and Gibbs. The idea in making this change is that the continuous iron core needs fewer current turns to produce a given induction, and this is generally considered to be of the first importance. With the object of getting the necessary excitation as small as possible, makers give the iron core as large a cross-section and as short a length as possible; and the tendency of designers is to increase the iron and diminish the copper of their transformers. The question of loss of power in heating of the cores does not appear to receive enough attention, and the object of this Paper is to point out that many common designs produce very inefficient transformers, and that in many cases a particular form of "open circuit" transformer is the best.

If a transformer with a full load output of 1,000 watts has a loss of 50 watts in the copper and 150 in the iron, its full load efficiency is 83·5 per cent. But suppose it is put in a house wired for, say, 17 lamps, the full load is on only very occasionally, about half the lamps being the usual maximum. The proportion of the lamps lighted to those wired varies. Some authorities take it that the average is equal to all the lamps on one hour a day; others say three or even five hours a day. If the full load is on two hours a day, and the transformer stands idle, merely keeping its iron hot all the rest of the time, its average efficiency is only 35 per cent. Many will at once say that the loss of 150 watts in a 1,000-watt transformer is absurd, and that modern transformers work at something like 98 per cent. full load efficiency. The figures generally given by makers are so obviously impossible that one is driven to conclude that the loss in iron is not measured.

As a matter of fact, the measurement of this loss is no easy matter. Before bringing forward a paper like this, it might be said that I ought to produce a number of accurate data, giving the loss at various inductions at various frequencies. Unfortunately, I cannot do so. We must, therefore, rest content with Prof. Ewing's determination of the curve of a single specimen of iron magnetised very slowly. No doubt it is perfectly accurate, but we want a great many curves taken with different samples of commercial iron, and perhaps different frequencies.

It is commonly assumed that a low induction should be used in transformers, because the heat lost per cubic centimetre of iron per cycle is then less; but it is forgotten that more iron is then needed. The volume of iron needed does not vary inversely as the induction; it increases quicker, as the iron is bent round the wire coils. The copper coils have also to surround more iron if its section is increased, and this entails more loss over resistance. On the other hand, the loss per cubic centimetre of iron increases more quickly than the induction, but not much more quickly, so that it may often be advisable to use a high induction.

Before going farther, it will be well to explain some of the terms used in this Paper. The square root of the mean square of the electromotive force is called the virtual electromotive force; so that an electrometer or non-inductive voltmeter measures the virtual electromotive force. The square root of the mean square of the current, or the current as measured by a dynamometer, is called the virtual current. Thus the product of the virtual electromotive force and virtual current on a non-inductive resistance give the real power, and so on. Roughly speaking, the virtual current and electromotive force may be taken as 10 per cent. greater than the mean electromotive force. Similarly, the virtual induction is measured by the virtual electromotive force

* Paper read before the British Association in Section G, Newcastle-on-Tyne, September, 1889. This Paper was discussed jointly with those of Major-General Webber and Mr. Killingworth Hedges. A full report of the discussion will appear in our next issue.

Digitized by Google

it produces. The mean induction need never be considered, as the question of heating depends on the maximum induction. The virtual induction is thus a maximum of about 10 per cent. less than would be necessary to give the corresponding mean electromotive force. The maximum induction again depends on the excitation, and not on the mean excitation. To get a maximum induction of 1 needs a maximum current of 1; it needs a mean current of about $\frac{2}{\pi}$ or ·64, or a virtual current of about $\frac{1}{\sqrt{2}}$, or about ·7. But a maximum induction of 1 is equal to a virtual induction of about 1·1, so that a virtual induction of 1 needs a virtual exciting current of about ·64. As an example, suppose a long core of one centimetre cross-section wound with wire, and suppose with a direct current one ampere per centimetre produced an induction of 10,000. If the direction of magnetisation alternated perfectly uniformly at a frequency of 2,500 per second, it would induce one volt per turn of wire round it. But if the magnetisation does not increase and decrease perfectly uniformly, the mean electromotive force will remain one volt per turn, but the virtual electromotive force will be greater. Take now the case of an alternating current, and find what virtual exciting current will be needed to induce one virtual volt per turn at a frequency of 2,500. The virtual induction needed will be 9,000. This will need a maximum exciting current of ·9, or a mean current of ·9 × ·64, or a virtual current of ·9 × ·7, or of ·64. If the direct exciting current of 1 lost 1 watt in a given length of wire, the corresponding alternating current will lose only about ·4, or less than half.

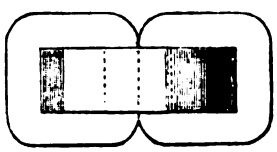

Fig. 1.

In making calculations to find the proportions which give highest efficiency it is clear that the interlinked coils must be as in the figure, in which the single link may be either the copper or the iron. If the cross-sectional area of the single link is equal to that of the pair, the pair will have less volume. If the waste of power per cubic centimetre of iron is greater than that of the copper, the wire will take the form of a pair of links, and the single link will be the copper wire. To get the best result the cross-section of the coil and core will be very nearly, but not quite, square. In the following calculations they have been assumed to be square, which can make no perceptible difference in the efficiency, and makes the calculations easier by removing two variables. The problem now proposed is: Given the desired output of the transformer, to design it to give the highest efficiency. Call the side of the section of the iron core x, and the side of the section of the copper core z. All the other dimensions of the transformer depend on x and z. We now have to find the loss in the transformer in terms of known quantities, and of x and z, and have then to choose x and z so as to make this loss as small as possible.

The waste in the iron core is equal to the waste per cubic centimetre of iron multiplied by the volume of the iron. Call the loss per cubic centimetre at the induction and frequency under consideration l. Then

$$\text{Power spent in core} = l\,x^2\,(4\,z + 2\,x) = 4\,l\,x^2\,z + 2\,l\,x^3.$$

The loss in a cubic centimetre of copper varies as the square of the current density. The most economical current density ought, properly speaking, to be determined by taking the current density as a variable; but it is generally so high that the coils would get hot. At first sight it may seem strange that a piece of apparatus that gets hot can be more efficient than one that keeps cool; but it must be remembered that the temperature depends on the facility for dissipating the heat, and a large transformer can lose more heat by radiation and convection than a small one, and can thus keep cool, though less efficient. Similarly a dynamo that gets hot is not necessarily inefficient. Heating is inadmissible on the score of durability and safety, so a current density must be assumed that will not cause excessive rise of temperature. The current density can generally be settled beforehand, as the size of the coils will be roughly known, and a safe density can be taken. If the loss per cubic centimetre of copper, with a current density of one ampere per square centimetre, is called p, the loss per cubic centimetre of copper is $p\,d^2$, d being the density in amperes per square centimetre. As the output is known, and the current density is assumed, and the thickness of insulation is also known, the proportion of copper to the whole volume of the coil is known. Call this k.

The loss in the copper is then $k\,z^2\,p\,d^2\,(4\,x + 4\,z)$, so the total loss in the transformer is

$$4\,l\,x^2\,z + 2\,l\,x^3 + 4\,k\,p\,d^2\,x\,z^2 + 4\,k\,p\,d^2\,z^3.$$

In this expression the extra loss of power due to the magnetising current in the primary coil is neglected, as it is exceedingly small. The magnetising current is itself small, and differs in phase, roughly, a quarter of a period. Thus, if the magnetising current were even 10 per cent. of the full load current, the full load loss in copper would only be about 1 per cent. more than here allowed. If B_v is the virtual induction in the core, and n the vibrations per second, $4\,B_v\,n \times 10^{-8}\,x^2$ is the electromotive force per turn of primary or of secondary wire. The total electromotive force is $4\,B_v\,n\,x^2 \times 10^{-8}$ multiplied by the number of turns in the primary or secondary coil. The output of both coils, or twice the output of the transformer, or $2\,P = 4\,B_v\,n\,x^2 \times 10^{-8}$ multiplied by the ampere turns in both coils. The ampere turns $= k\,d\,z^2$, so that

$$2\,P = B_v\,n \times 10^{-8} \times k\,d\,x^2\,z^2;$$

$$\text{therefore} \qquad z = \frac{1}{x}\sqrt{\frac{2\,P}{4\,B_v\,n\,10^{-8}\,k\,d}},$$

Call the coefficient b, then $z = \frac{b}{x}$

The total loss is thus

$$4\,l\,b\,x + 2\,l\,x^3 + \frac{4\,k\,p\,d^2\,b^2}{x} + \frac{4\,k\,p\,d^2\,b^3}{x^3},$$

$$\text{so that} \qquad 4\,l\,b + 6\,l\,x^2 - \frac{4\,k\,p\,d^2\,b^2}{x^2} - \frac{12\,k\,p\,d^2\,b^3}{x^4} = 0;$$

$$\text{or} \qquad 3\,l\,x^6 + 2\,l\,b\,x^4 - 2\,k\,p\,d^2\,b^2\,x^2 = 6\,k\,p\,d^2\,b^3.$$

This can be solved as a cubic equation for each transformer wanted, or by trial. In practical work an exact solution of such an equation is not required, as any dimensions that even approximately fit the equation give sensibly the same efficiency. Thus x can be made a round number of millimetres, or of eighths of an inch. If a complete table of transformers is wanted it may be shorter to make a finite difference table increasing x^2, the cross-sectional area of the core by jumps of, say, two square centimetres. Or the table may be calculated directly with the aid of a slide rule. In practical work a great deal of time may be wasted, not on legitimate calculations, but on work containing clerical errors, and on trying to find out the mistakes and to see how they got there. Any one who is an inaccurate worker may therefore prefer to make a table in such a way that if the last term is right all the rest must be right too.

A complete set of closed circuit transformers was designed by me for Messrs. Crompton and Co., the waste in copper and in iron and the cost of material and the efficiencies under various circumstances being worked out. In this case the loss in iron was assumed to be about half as much again as in this Paper, as that seemed a fair margin for practical work, though it might not be assumed for argumentative purposes. Most of them were calculated for a frequency of only 33 per second; as I found that led to great saving in the manufacture of the dynamo, and led to small extra cost and loss of efficiency in the transformers, some of these tables may be shortly discussed before going farther. The induction is taken at 14,000, and the loss is taken at 14,600 ergs per cubic centimetre per cycle, or ·024 joules per cubic inch.

* This line at 1,000 to 50 volts.

The tables were calculated with the object of being useful, so the dimensions are in inches.

In Table I. the first column gives the number of 60-watt lamps. The second and third give the diameter or size of wire in inches in the primary and secondary coils. The dagger means that the wire is square. The fourth and fifth give k and b, which are mere coefficients as before. The column x gives the side of the core, and z the side of the coil in inches. The next columns give the loss of power in watts, The cost of material in the last columns is in shillings, taking iron at 3d. and copper at 9d. a pound. Table I. is calculated for transformers on full load the whole 24 hours.

It must be borne in mind that these tables do not give sizes for actual transformers, but act as guides to give the dimensions that should be approached.

Table II. is calculated for 16 hours a day. This is to say, the transformer is supposed to have the secondary open a third of the time. The transformers have then to be re-designed, as the loss in iron becomes relatively more important. It will be noticed that the efficiency begins to fall off and the price to go up. If transformers from Table I. were used only 16 hours a day, the efficiencies would be lower than those in Table II. Tables III. to VI. need no further explanation. It is well to point out that a great deal depends on the way the time is estimated. Full load one hour a day is not the same as half load two hours a day. Half load two hours a day would have less copper waste, so to make the best transformer the copper would be increased and the iron lessened. These last transformers are really absurdities: the 50 lights in Table VI. has an average efficiency of only 60 per cent., and costs about £20 for material only. The E.M.F. has so far been assumed to depend only on the induction in the iron core, but when the core is so small and the coils are so large this is no longer even approximately true, as will be explained later.

Table VII. is to show what may be gained by transforming from 1,000 to 50 volts instead of from 2,000 to 100. The difference is due to the difference of room taken up by the insulation. The table is made for 50-light transformers, designed for the various times of full load. The column of efficiencies at 2,000 and 100 volts is for transformers designed for these volts, not for the same transformers merely re-wound. The difference would be greater if the same transformer were used in each case. It will be seen that the efficiencies and costs are very little reduced by using low tensions; but as the percentage fall of E.M.F. on the lamps is increased by using the most efficient transformer, it would be best not to design the low tension transformer with a view to efficiency only.

Table VIII. shows the effect of using transformers for time loads for which they are not intended. Thus a full time 50-light transformer has an efficiency of 92 per cent. on full time, but only 44·2 per cent. with full load an hour a day. The 50-lighter, specially designed for one hour a day, has an efficiency of 60 per cent., but at 24 hours a day it only rises to 82·3 per cent. The fall of E.M.F. on the lamps is also quite out of the question.

Table IX. shows the percentage fall of secondary E.M.F. at full load. The Table, like those before it, is for a frequency of 33. The last two columns show the advantage of using 80 per second. The loss in a 50-lighter is 2·76 instead of 3·42 per cent. in the case of 24 hours, and 14 per cent. instead of 19·5 for the 1-hour transformer. The 1,000-lighter would be for substations, and would never have its primary on and its secondary off, so it is taken for 24 hours only. The fall is 1·5 per cent. at 33, at 1·15 at 80.

It is needless to remark that when the variation of terminal E.M.F. is great, it is very much more important than the efficiency of the transformer itself as it affects the efficiency of the lamps, and thus of the whole system.

Table X. is for three transformers for a frequency of 80. The 1,000-lighter has an efficiency of 97·2 instead of 96·75, or an increase of ·45 per cent. Its cost of material is £13. 10s., instead of £20. 10s.

The efficiency of the full time 50-lighter is 93 against 92, and its cost of material is £1. 13s. 6d., against £2. 8s. 6d. This must, of course, not be confused with the cost of the transformer, which includes many other items.

(To be continued.)

A NEW THERMOMETRIC SCALE.*

BY PROF. G. FORBES AND W. PREECE, F.R.S.

The recent Electrical Congress at Paris has adopted the *Joule* as the unit of work and the *Watt* as the unit of power. The following definitions were unanimously accepted:—The practical unit of work is the *Joule*. It is equal to 10^7 C.-G.-S. units of work. It is the energy expended during one second by an ampere in an ohm. The practical unit of power is the *Watt*. It is equal to 10^7 C.-G.-S. units of power. The watt is equal to a joule per second.

The *therm* as the unit of heat, which was proposed by the British Association Committee, at Bath, last year, did not commend itself to the French members. They preferred for the present to retain the term *calorie*, notwithstanding the confusion from their being two units of that name. It is said there is only one calorie in the C.-G. S. Centigrade system. But the question arose, is there any need for either the therm or the calorie? Cannot the joule be made the thermal unit also, for the latter is only a unit of work? The heat generated in T seconds by C amperes flowiug through R ohms, or driven by E volts, is $C R T = E C T$ joules. If we take the mechanical equivalent of heat as approximately 42,140,000 ergs, or 4·2 joules, it means that 4·2 joules will raise one gramme of pure water at 4°C. one degree; or, in other words, that one joule expended on one gramme of pure water will raise its temperature ·238°C.

We have here the true scientific mode of forming a C.-G.-S. thermometric scale. If we take the fiducial points of freezing and boiling points of pure water at normal pressure on a column of mercury as usual, and divide the distance into 420 divisions, then each division is a true C.-G.-S. unit of temperature, and will be passed by the expenditure of one joule per gramme of water. Instead of employing degrees of temperature we can thus use these units of temperature, and we can replace the angular symbol x° by t or θ.

Thus to raise one gramme of water from freezing point to boiling point requires 420 joules, or to raise it to boiling point from 62 units it requires 358 joules. There would be no necessity for any coefficients, and calculations would be simplified.

Degrees Centigrade would be simply converted into three units by multiplying by 4·2, and degrees Fahrenheit by deducting 32 degrees and multiplying the remainder by 2·33. An objection to such a scheme has been raised by Prof. POTIER, of Paris, and it is that the mechanical equivalent of heat has not yet been determined with sufficient accuracy to justify its adoption as final. He thinks it wrong by nearly 1 per cent. The principal measurements are—

Joule (1878)	4·1624	Violle	4·2701
Hern	4·2485	Regnault	4·2877

This ought to be a reason to re-examine the question, and with our existing knowledge of the ohm and the ampere we ought to be able to derive the joule with an exactitude that will satisfy the scientific world.

* Paper read before the British Association in Section A, Newcastle-on-Tyne, September, 1889.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny. Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

'THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

SOME ELECTRICAL PAPERS IN SECTION G.

The wide extent as well as the singular diversity of parts which, in the drama of modern civilisation, electricity is called upon to play, was well illustrated by the series of papers which were read on Monday last in Section G. before the British Association. For the lighting of our streets and houses, for the purification of our sewage, for the transmission of articulate speech betwixt city and city, or for the propulsion of tramcars or river launches, it is to electricity that we now turn as affording an appropriate solution. It is worthy, perhaps, of note that the reasons why we find it advantageous to call electricity to our aid are almost as diverse as the purposes to which it is applied. Sometimes, as in telegraphs and telephones, there is practically no other agent to which the duty can be entrusted; sometimes we employ electricity because, if more costly, it does the work in an incomparably better manner; in other cases it is because it is the cheapest, whilst in others it is the most rapid or the most efficient means at our disposal. Those who have closely watched the recent developments of the industrial applications of electricity can scarcely doubt that we are approaching a period in which its special modes of utilisation, apart from the great departments of electric lighting and the transmission of energy, will undergo an extension of which at present we have perhaps little conception. The electrical refining of sugar, as presented by FRIEND and Co., was a palpable fraud, which ought never to have deceived the merest tyro in electro-chemistry; but the case is very different when we come to such operations as the purification of sewage, the method of electric bleaching, the electric welding and refining

Digitized by Google

of metals, the separation of aluminium, the modern methods of plating with platinum, cobalt, and other costly metals, and to this we may perhaps add the application to the tanning of hides. All these processes, and many others which might have been included, important and diversified as they are, form probably but a mere fraction of the special applications of the electric current in our arts and manufactures, of which we may within a comparatively short period witness the introduction. As soon as the extension of central station lighting has familiarised the public mind with the presence of electricity, and has rendered it generally available, we anticipate a considerable impetus to its employment, by the discovery of channels for its utilisation which may not hitherto have seemed worthy of investigation.

For this reason, amongst others, we think it a matter for congratulation that the seven electrical papers in Section G., although, with one exception, they afforded but little novelty for electricians, have yet admirably served the purpose of bringing before the public mind some of the most striking and most important instances of the modern applications of electricity. To the remark that novelty was lacking, there is, however, one important exception which must necessarily be made. Had we heard from Mr. SWINBURNE a Paper which did not contain, at the very least, one startling and suggestive novelty, it would have been—well, a startling novelty in itself. Mr. SWINBURNE'S Paper on Transformers deserves the most thorough and attentive consideration, for, if he be right, there is not a single transformer now in the market which is constructed in accordance with sound economic and scientific principles. Whatever may be the actual value of Mr. SWINBURNE'S revolutionary proposal to return to the open-magnetic-circuit type — and on this we do not at present express an opinion—it is, at least, certain that to design a transformer with a view solely to obtaining maximum efficiency at maximum load is, *as a rule*, totally wrong. A moment's consideration will, however, show that Mr. SWINBURNE was not quite right in saying that this method of design is *always* wrong. Transformers must, in fact, be designed with direct reference to the class of work which they will be called upon to do. For shop lighting, for instance, we should in general aim at getting maximum efficiency with maximum load, whilst for private houses about one-third load is probably the point at which the efficiency may with advantage be highest. To use one type of transformer for all conditions is an obvious error. The result of Mr. SWINBURNE'S research, on the most economical proportions of iron and copper, has been to lead him, as already hinted, to return to the open magnetic circuit; by this device he, of course, saves much of the energy now lost in hysteresis, but he is obliged at the same time to diminish the section of the iron and increase the quantity of copper in order to retain the magnetising current within economical limits. Whether this is or is not the best method of diminishing the waste of power in the primary circuit when the secondary circuit is unclosed, is as yet an open question. The question is one which is already attracting serious attention, and some very different solutions are being attempted. At Zurich, for instance, where Messrs. BROWN, of Oerlikon, are putting down a central station with "Kapp" alternating plant, the houses are supplied from a limited number of sub-distributing stations. Each of these stations contains two transformers of different sizes, one for the day and the other for the night service. Another solution which must often have occurred to those engaged in this work is that of arranging some device whereby the primary coil is only brought into circuit at the moment when the secondary is closed, and is again switched out when the last lamp is turned off. The problem is not quite an easy one, but it can doubtless be solved in some way, and, indeed, we understand that the London Electricity Supply Company are now experimenting in this particular direction. Of course if, as is very possible, Mr. SWINBURNE'S solution be the right one, we shall be spared the trouble of any such supplementary devices or the expense of extending the secondary circuits to the distributing mains.

The mention of supplementary devices naturally brings to our recollection the important Paper read by Major-General WEBBER on the installation at Chelsea, and which installation at first sight seems to be one grand collocation of supplementary devices. We do not, however, say this by way of reproach, for of one thing there can be no doubt, and that is that the automatic appliances designed by the staff of the Electrical Power Storage Company discharge their duties with the most praiseworthy accuracy and efficiency. Nearly two years ago we witnessed at Millwall the working of the first set of automatic switches designed for this purpose, and constant experiment and experience since that date has enabled Mr. F. KING and his colleagues to bring the design to a state of perfection which is really marvellous. Complex and elaborate it undoubtedly is, and apparently so it must always be if it is to fulfil the required conditions, but if this be entered as a serious objection to the system, there remains still one redeeming feature, namely, that (according to the inventors) no possible breakdown in the automatic mechanism can result in any even partial breakdown of either the generating or the discharging circuits.

We had meant to say a few words upon the interesting Papers of Prof. FORBES, and Messrs. PREECE, MANVILLE and WEBBER, but space does not permit, and we must conclude by repeating that, in spite of their comparative want of novelty, nothing but good can result from the reading of Papers of this class before the British Association.

REVIEWS.

The A. B. C. of Electricity By W. H. MEADOWCROFT. (Manchester: Heywood, 1889.)

This is a little book of 108 pages in a somewhat prettily executed cover, illustrating a group of incandescent lamps and a dynamo supplying them with current, and bearing underneath the pictorial design the magic inscription, "Endorsed by Thomas A. Edison."

On opening the book we find that it is well-printed, on very good paper, and we find, moreover, a letter from Mr. Edison in which he states that he has read the MS. of Mr. Meadowcroft's work and finds that the statements which he has made in it are correct, from which we conclude that the inscription printed on the cover applies to the contents of the book, and not, as might be supposed, to the design below which it is placed.

We are informed in the preface that the volume has had an extensive circulation in America, and that it is intended to give to young people of the age of fourteen years and upwards a general outline of the science of electricity together with some idea of the telegraph, the telephone, and electric lighting.

When we look beyond the preface we find that the language in which the book is written is such as might be adopted in this country in addressing children of from six to eight years of age, and which would, we fear, be resented by English schoolboys or school-girls, of the age of fourteen or even less, and we hardly think that even Mr. Edison's endorsement would be sufficient to reconcile them to it. It may, however, be different in the States, where we understand it is generally believed by the uninstructed that Mr. Edison is the inventor of electric lightning, of the telephone, and possibly even of the telegraph, if, indeed, he was not the discoverer of electricity itself. Mr. Edison's endorsement may therefore very possibly have led

Digitized by Google

many young people in the States to peruse the book with eagerness and to imbibe with implicit confidence the statements vouched for by so great an authority. For our own part we do not look for profound scientific knowledge from that very ingenious inventor, but we own that we were surprised to meet, in a book which may to a certain extent be regarded as his profession of electrical faith, with a statement such as the following, which we quote from the second page of the text: "We all know that if you have a pound of water you must have something to hold it because it has weight and consequently occupies some space. But electricity itself has no weight and therefore cannot occupy any space." We do not ourselves see the cogency of this reasoning. Put into the form of a logical proposition it stands thus—

Everything that has weight occupies space.
Electricity has not got weight;
Therefore, electricity does not occupy space.

An exactly similar argument would be the following:—
All men are mortal.
Horses are not men;
Therefore, horses are immortal.

On the same page we are told that pressure is reckoned as so many pounds to the square inch of water. We should very much like to know what a square inch of water means; of course, on the assumption that the author is writing for the inhabitants of our ordinary world of three dimensions, and not for the denizens of Flat Land, where everything has two dimensions, so that material bodies are measured in superficial measure. A few pages further on we are told that the pressure in a boiler is measured or calculated in pounds, just as the pressure of water is measured. Here, as before, reference to the square inch is required, although the author does not give it to us, but it should be a square inch of boiler surface, just as in the former case it should have been a square inch of the surface on which the pressure was exerted.

After this we are not surprised to learn that a hundred pounds of steam pressure can be changed to electricity at 100 volts pressure, or that electricity can be turned into heat.

The concluding paragraph on magnetism is worth quoting. "The only way we can get electricity to do useful work for us is to put some resistance or opposition in its way. So you see that if we make it travel through the wire around the iron or steel there is just enough resistance or opposition in its way to give it work to get through the wire, and this work produces the peculiar effect of making the iron or steel magnetic."

It is quite true that electricity will only do work when there is some resistance in its way, that is to say when we give it something to do; but the author is evidently under the impression that the best way to make electricity do work in one direction is to give it a resistance to overcome somewhere else, which is much the same as saying that a man pulling water out of a well by means of a bucket would be assisted in his work if half a hundredweight of lead were fixed to the bottom of the bucket.

A current passing round a piece of iron has to do work in magnetising it, but the work is done in the interior of the iron. The magnetising effect of the current is most decidedly not assisted by increasing the resistance of the wire through which it flows, but, as every electrician knows, is diminished, for the simple reason that when a given E.M.F. is maintained between the ends of a wire the effect of increasing the resistance is to make less current flow through the wire, so that there is a smaller magnetising effect.

The author's practical descriptions are decidedly better than his theory, but even here his explanations are not always satisfactory. For example, he informs his infantile, or other readers, that if the connecting wires were attached directly to the ends of the revolving armature coils, they would be broken off, and that this catastrophe is avoided by the use of a commutator.

We, in our innocence, had always supposed that continuous sliding contacts were used for this purpose, and that the object of a commutator was to rectify the alternations of the current. The author's explanations of the action of the electric current in making a carbon filament incandescent is too good to be omitted:—

"You see it is a struggle between the carbon and the electricity, the current being determined to go on, and the carbon trying to keep it back, and in the end the electricity being the strongest gets the best of it; but the struggle has been so hard that the carbon has been raised to a white heat, and so gives out a beautiful light, which continues as long as the current of electricity flows."

We have not infrequently met with explanations of a very similar character in the papers of examinees striving after the, to them, unattainable prize of a Science and Art Department certificate in the elementary stage of electricity and magnetism.

THE MEETING OF THE BRITISH ASSOCIATION.

ON HYSTERESIS IN THE RELATION OF STRAIN TO STRESS.*

BY PROF. J. A. EWING, F.R.S.

It is now well known that when an iron wire is subjected to the alternate application and removal of tensile stress, many times repeated, certain of its qualities which are affected by the changes of stress exhibit hysteresis with regard to the changes of stress. If the load is cyclically varied between definite limits these qualities do not have the same values at corresponding intermediate points during the application and removal of load; there is a hysteresis or lagging in the change of quality which is some cases appear to be of a static character—that is to say, independent of the time-rate of variation of stress. Conspicuous instances of this action are seen in the change of magnetic and thermo-electric qualities under change of stress, some of which have been described by the author in former Papers.

It is natural to look for an effect of the same kind in the extension and retraction which the wire undergoes. We should expect that, after the change of loads has been frequently repeated, so that a cyclic *régime* is established, the wire will, for any value of load intermediate between the two extremes, be longer during unloading than during loading. Evidently, if such an effect exist, it must be small, as it is well known that the proportionality of strain to stress which is expressed by Hooke's law is at least approximately exact. Sir W. Thomson's experiments on the damping of torsional vibrators have long ago shown that an action of the kind spoken of occurs in quickly-performed cycles of torsional strain; but it does not seem to have been looked for in slow cycles of longitudinal pull.

The author has, with the assistance of one of his students, Mr. D. Low, looked for the effect in question, and has found it, not only in iron, but in steel, brass, and copper wires. He has not yet examined other metals.

The experiment consisted in observing, with much optical magnification, the extension of a very long piece of wire, directly loaded with lead weights. The wire was hung from a rigid support in a testing flue or recess, built in the wall of the laboratory, and extending up through four storeys. At a distance of 806 centimetres below the top a small clamp was fixed on the wire, and this formed the support of the back foot of a little tripod, the feet of which consisted of three needle points about an inch apart. The two front feet rested in a slot and hole in a fixed shelf which stood in front of the long wire. The tripod carried a plane mirror which became tilted forward or backward as the wire extended or retracted. Readings were taken by a telescope of the reflected scale of a levelling staff placed vertically at a distance of some 5 metres from the mirror. The staff was graduated to $\frac{1}{100}$th of a foot, and it was easy to read by estimation to $\frac{1}{1000}$th of a foot, which corresponded to 0·000000102 of the length of the wire. At first a fixed shelf was used to support the two front feet of the mirror, but the effects of temperature were found to be excessive, although the greatest care was taken to shield the wire from draughts, and the plan was resorted to of hanging the shelf from two adjacent wires of the same material, suspended from the same support as the wire which was to be stretched. In this form the method of optical multiplication was nearly the same as one used by Mr. Bottomley in recent experiments on the extension of loaded wires by heat.

The first wire tested was of iron, in the hard-drawn state, 1·08 millimetre in diameter. A weight of 14lb. was kept permanently on it, and an additional weight of 20 kilometres was applied and removed many times. Then readings were taken at intermediate loads (the extreme load caused so much tilting of the mirror that readings could not be taken throughout the whole range). At 10 kilometres (the middle of the cycle) on the way up the scale reading was 2,340; with the same weight on the way down it was 2,305. The difference, due to hysteresis, is 35, or 0·00000357 of the length. The whole extension per kilometre was 533 scale divisions, so that the change of length due to the full load of 20 kilometres was $20 \times 533 = 10{,}660$ scale divisions. Hence the amount of difference in length at the middle position or, 10 kilometres, in the loading and unloading processes was $\frac{35}{10660}$, or, say, $\frac{1}{300}$th of the whole extension between the extreme load. Another way of stating the result would be to say that the extension had the same value at 10·066 while the load was being increased as it had at 10 kilometres while the load was being diminished; the effect of hysteresis is equivalent to a difference of 66 grammes in the load.

Further experiments were made to test how far this hysteresis depends on the time rate of loading and unloading. In the above case, the cycle of load had been performed as quickly as was practicable, the only pauses being at 10 kilometres on the way up and at 10 kilometres on the way down. It was found that even when the pause at 10 kilometres lasted for two hours no distinct change took place in the readings. So far as this experiment showed, the hysteresis is persistent. It appeared, however, that pauses at the extremes of load has the effect of increasing the difference of readings at the middle. In a slowly performed cycle, where a pause of about three minutes was allowed at each step (of two kilometres) in the processes of loading and unloading, the difference of the readings at 10 kilometres was about 50 scale divisions instead of the 35 divisions observed in the former case.

A similar trial was made with mild steel wire, previously annealed and then hardened by the imposition of a load much greater than the load afterwards used in the testing cycle. Here the wire was 0·94 millimetres in diameter. There was, as in a former case, a constant load of 14lb., and the cycle was made by applying and removing 12 kilometres. At six kilometres the readings were 4,695 and 4,726; difference, 31. The extension per kilometre was 750. Hence the hysteresis is $\frac{31}{12 \times 750} = \frac{1}{290}$ of the extension due to the whole load. With long pauses at the middle load the hysteresis appeared to be reduced to 27 scale divisions, or $\frac{1}{333}$ of the whole extension.

Next, a hard wire of high carbon steel was tested, 0·72 millimetres in diameter, by having 14lb. permanently on, and loading and unloading 12 kilometres. At six kilometres the readings were:—"Up" 9,220, creeping to 9,240 in two hours; "down" 9,400, creeping to 9,370 in two hours. Differences, 180 and 130.

The extension for 1 kilometre was 1,290, so that the above differences correspond to $\frac{1}{86}$th and $\frac{1}{119}$th of the whole extension respectively. It is remarkable that the hysteresis is decidedly greater here than in the wires previously tested.

A brass wire 1·08 millimetres in diameter tested in the same way with 12 kilometres gave readings 6,990 and 7,114 at 6 kilometres, difference = 124, which was equivalent to $\frac{1}{107}$th of the whole extension, since the extension for 1 kilometre was 1,100 scale divisions.

With a copper wire 1·15 millimetre in diameter, loaded with 10 kilometres, the readings at 5 kilometres showed a difference of 52 scale divisions, equivalent to $\frac{1}{158}$th of the whole extension

These experiments make it clear that in conditions of loading such as those they deal with, there is a decided departure from Hooke's law, one effect of which is that some work is done upon the material when it is put through a cycle of stress change. If the relation of strain to stress were represented graphically, the curves would form loops enclosing a certain area. This result has a sufficiently obvious bearing on the conclusions of Wöher with regard to the deteriorating effect of repeated variations of stress.

ELECTRIFICATION OF AIR BY COMBUSTION.*

By MAGNUS MACLEAN, M.A., F.R.S.E., and MAKITA GOTO, of Tokyo, Japan.

About the middle of April last a series of observations was commenced within the Natural Philosophy Class Room and Apparatus Room, the Bute Hall, the University Tower, and various other rooms in the Glasgow University Buildings, under the instructions of Sir William Thomson, for the purpose of endeavouring to find—(1) the state of the air inside a room as regards electrification, (2) the relation between the electrification of air within a building and the atmospheric potential in its neighbourhood outside, and (3) the causes which produce or change the electrification of any given mass of air.

Up to the 3rd of July, 106 such observations were made, and although we drew curves and compared them carefully, no definite relation could be discovered between the electrification of different rooms in the University, or between the electrification of any of the rooms and the external potential. After that date our experiments were chiefly directed to the finding out of the causes which changed the electrification of the air of the room in which we experimented, and we give in the present Paper a summary of the results which we have already obtained. On the 15th of July Sir William Thomson communicated a Paper on "Electrification of Air by Flame" to the Royal Society of Edinburgh, in which the effect of an ordinary paraffin lamp—the only flame we had tried up to that date—is described. From that Paper we quote the following:—

"In one ordinarily unused room (the Physical Apparatus Museum) 31½ feet long by 24 feet broad and about 20 feet high, practically quite free from any sensible disturbance by electric light wires, or by electrical operations being performed in the Laboratory, a remarkable result has been observed within the past fortnight. The electric potential of a water-dropper, having its nozzle at the centre of the room and about 7 feet above the floor, was always found about two volts negative at the commencement of the observations, and always increased to about 9 volts in the course of the first twenty minutes of a series of observations lasting generally forty minutes. During the last

FIG. 1

The method of observation was as follows:—An insulated water-dropper (*see* § 262. Papers on Electrostatics and Magnetism, by Sir W. Thomson) was connected to one of the terminals of a Thomson quadrant electrometer, the other terminal being connected to the case of the instrument and to a gas-pipe for earth. A paraffin lamp and scale were used, and the deflections were read in the usual manner by observing the reflected spot of light.

Two such arrangements were used, one in one room and the other in another room, or both in one and the same room with one water-dropper in the centre of the room and the other discharging out through a window as described in the article quoted above. Readings were taken every half-minute, generally for 30 or 40 minutes, and by comparing watches beforehand it was possible to obtain simultaneous readings of both instruments, however far apart the different rooms were.

twenty minutes of the series the potential remained somewhat nearly constant at 9 volts. Within the room, two quadrant electromoters, each with an ordinary paraffin lamp and scale, were used, one of them for the outside water-dropper and the other for the water-dropper within the room.

"Towards ascertaining the cause of this change an observation was made on the 4th July, between 10 and 11 a.m. The lamps were both extinguished, and one of them was lighted by a lucifer match every five minutes for the purpose of reading the electrometer deflection. It was found that in these circumstances there was not the increase of negative potential which had been found in every previous series of observations in the same place, and with all other circumstances the same except the burning of the lamp. This single observation seemed to prove conclusively that the burning of the lamp gave a negative charge to the air of the room."

Arrangements were made after this to place the electrometer and its lamp outside the room, and observations made, with no

* Paper read before the British Association in Section A, Newcastle-on-Tyne, September, 1889.

Digitized by Google

lamp burning inside, or with one or more lamps burning inside. A large number of experiments has fully confirmed the result stated above.

Curve No. 1. (Fig. 1) is one of many which will serve to show the effect. The observation was made on the afternoon of the 9th of August in the English Literature Class-room, which is on the ground floor of the University. It is 37ft. by 34ft. and 24ft. high. The curve shows that as soon as the windows were opened the negative electrification began to be diminished, a change which was due, no doubt, to the coming in of the external air.

After this date the paraffin lamp was dispensed with, and a telescope was used to observe the deflections of the electrometer needle by the mirror attached to it. In all subsequent experiments, water-dropper, electrometer, and telescope are in the same room, as it was found that the effect of one or two persons in the room was practically nothing. The observations were made as follows:—The water-dropper having been filled and allowed to run, the variations of the electrometer needle were observed by the telescope for five or ten minutes. Then the burning substances were placed generally on the floor below the nozzle of the water-dropper, which is 7ft. above the floor, but sometimes in other parts of the room, and the observation continued for ten, twenty or thirty minutes.

The following is a list of various kinds of flames and fires which were tried:—Charcoal, paraffin lamp, coal gas, alcohol; coal both smoking and smokeless; lucifer match wood, ordinary paper (either with a flame or glowing); sulphur, magnesium, phosphorus exposed to air, electrometer match (blotting paper soaked with nitrate of lead). The first four in the list are arranged in the order of magnitude of their effect. With the exception of charcoal, alcohol, the smokeless coal, and glowing wood or paper, the effect of the other substances was distinctly to electrify the air of a room negatively. Alcohol and the smokeless coal have a doubtful effect. Burning charcoal electrifies the air of a room positively, and it does so quickly and largely. Curve No. 2 (Fig. 1) will show the effect. It was obtained in the Physical Apparatus Museum Room on the 23rd of August, and illustrates the effect not only of burning charcoal but of a burning paraffin lamp.

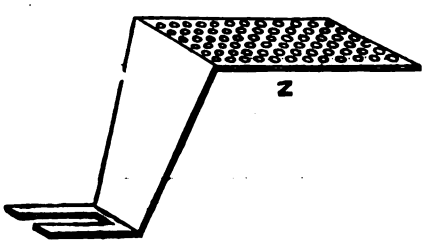

Fig. 2.

A number of observations of this nature satisfied us as to the effect of each burning substance on an enclosed mass of air. We reasoned that if a burning substance electrifies the air negatively, the substance itself must become positively electrified, and we devised the arrangement described below for testing this conclusion.

A strip of sheet copper about 3 centimetres wide and 7 centimetres long is bent into the form of a Z (Fig. 2). The lower end of the Z is joined to one of the terminals of the electrometer (Fig. 3), and the burning substance, or small copper lamp in which the substance burns, is placed on the upper end, which is perforated. The cylinder A, 25 centimetres long and 12 centimetres in diameter, also made of sheet copper, is joined by wire to the case of the electrometer, while it is made to surround, but not to touch, the Z piece with the burning substance placed on it.

Observations were made (1) when the cylinder is not surrounding the Z, and (2) when the cylinder is surrounding the Z. The results obtained when the cylinder is not surrounding the Z, though consistent as regards the sign of the electrification, are not consistent in the magnitude of the electrification obtained. It depends on the state of electrification of the air of the room at the time. For example, when by means of the water-dropper in the usual way the potential of the air of the room was found to be $1\frac{1}{2}$ volts negative, a burning paraffin lamp placed on the Z gave $\frac{1}{2}$ volt-positive, but when the water-dropper indicated that the potential of the air at its nozzle was 3 volts positive air, the paraffin lamp on the Z gave $1\frac{1}{2}$ volts positive. The results obtained with the copper cylinder surrounding the Z are, however, consistent in both these respects. For convenience of reference they are put in the following tabulated form:—

Substances.	Electrification.	Magnitude of electrification with the cylinder.
Charcoal	Negative	3 volts
Paraffin lamp	Positive	$\frac{1}{2}$ „
Alcohol lamp	„	$\frac{1}{3}$ to $\frac{1}{10}$ volt
Phosphorus exposed to air...	„	$1\frac{1}{2}$ volts
Sulphur	„	Variable, 1 to 2 volts
Magnesium	„	—
Lucifer match, wood, paper, burning with flame.....	„	—
The same, glowing.....	Negative	Same as charcoal
Electrometer match, glowing	Positive	Very variable
Blotting paper soaked with sulphate of copper, glowing.....	Positive or negative	Variable

The effect of an ordinary lucifer match is very interesting. While the match is burning with a flame the deflection indicates positive electrification, but after the flame ceases the electrification becomes negative, the effect now being that of glowing charcoal. The room in which all these last experiments have been carried on is a small room at the back of the Law Class Room, which is in the east quadrangle of the University and on the ground floor. It is 8ft. by 10ft., and 24ft. high. It was chosen because it is far removed from electric light* and telephone wires.

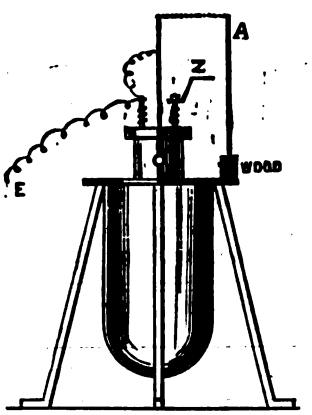

Fig. 3.

Preparations are now being made to test other burning substances in a similar manner, and to try these, as well as those we have already tried, under different conditions.

It is also intended to carry on the observations on natural atmospheric electricity, and to compare with the May and June results, which are not published as yet, because in all the observations a paraffin lamp was always used.

*The effect of the electric light wiring was tried on 24th April in the Natural Philosophy Class Room. The electrometer and water-dropper were set up on the Class Room table, and when the reading indicated about 4 volts negative, the negative lead of Sir William Thomson's house electric-light circuit, which passes through the Class Room, was joined to earth. This changed the deflection of the electrometer by 1 volt in the positive direction. When the positive lead was earthed, the deflection was changed by 6 volts in the negative direction. Putting on 16 electric lamps, eight on either side of the Class Room, changed the deflection by $\frac{3}{4}$ volts in the negative direction.

The Electric Railway on Ryde Pier.—The electric railway on Ryde Pier has proved such a decided success, that one line of rails is utterly inadequate to provide for the traffic. The company have therefore determined to lay down another line next year, and also to further improve the pier.

ON THE RELATIVE EFFECTS OF STEADY AND ALTERNATE CURRENTS ON DIFFERENT CONDUCTORS.*

BY WILLIAM HENRY PREECE, F.R.S.

1. Sir William Thomson, at the Bath meeting of the British Association, startled the electrical world by asserting that alternate currents entered a distance of only about three millimetres into the heart of a thick, round, copper conductor when the frequency was 150. This "Diffusion Law," as he called it, is based on the assumption that a current starts at the surface of the conductor and works its way radially inwards. It is dependent on the coefficient of self-induction and on the frequency—that is, on the number of complete alternations of positive and negative currents transmitted per second.

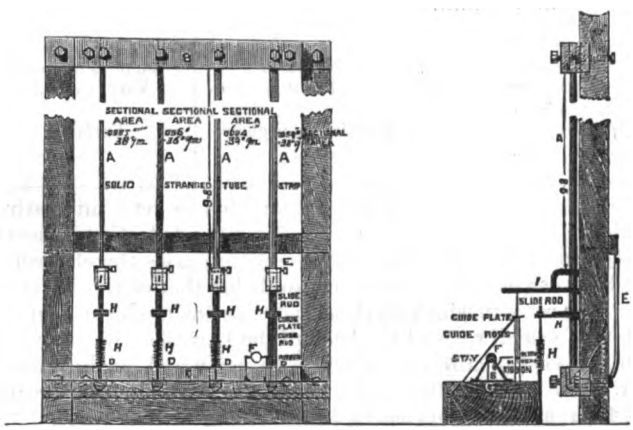

FIG. 1.

2. As this law has a most important bearing on the commercial value of systems of distribution dependent on alternate currents, it becomes most desirable to study the question practically. The verification of the law is almost beyond the reach of experiment. It occurred to me, however, that if we took conductors of different materials, such as iron, copper, lead, and platinoid, of easily measurable lengths and of convenient sectional areas, and transmitted through them measurable and variable currents, both alternate and direct, approximately similar to those used in practice, we should be able to study the question by observing the changes of temperature in the conductors, and we should at least observe any difference, if such existed, in the total expenditure of energy in the conductors under these different circumstances. Any addition or diminution of energy expended would give some indication of the operation of the law of diffusion in comparatively small conductors, without, however, determining the actual distribution of current density.

3. The Eastbourne Electric Light Company placed their machinery at my disposal. Messrs. Bolton and Son supplied me with copper, Messrs. Frederick Smith and Co. with iron, Messrs. John Fowler and Co. with lead, the London Electric Wire Company with platinoid, and Messrs. Elwell, Parker and Co. with accumulators and a specially-made converter. I was fortunate in securing the assistance of Mr. Lowrie, the engineer to the Electric Light Company, and of Mr. Gay, the assistant engineer, who constructed the apparatus and took and recorded the observations. The experiments were very numerous, very costly, and extended over a long period.

4. An extremely strong wooden frame (Fig. 1) was constructed, with a stout crossbar of iron at the top, B, which not only rigidly fixed one end of the conductors, A, to be tested, but also formed a terminal block for the currents. The lower end of the conductor dipped freely into an iron well, D, which could be filled with mercury at will by means of the tubes E, and acted as the other terminal. Stirrups and springs, H, were fixed so as to prevent the buckling of the conductors to be tested. A length of 9ft. 8in. (294·6 centimetres) was accurately marked off each rod, and a clamp, I, was fixed on to the conductor so as to transmit the expansion of the rod to the mirror apparatus F, which could be slid under each rod as it was tested. The construction of this mirror arrangement is more fully shown in Fig. 2. The mirror was deflected by the down thrust of the clamp on the rod, so that a thin metallic ribbon, passing over a pulley on the axis of the mirror, moved it with equal increments in all parts of the scale. A spring, S, brought the mirror back to zero. It reflected a ray of light from the oxyhydrogen lamp H, 20ft. 10in. long (635 centimetres), on to the curved screen N, upon which a scale was drawn such that one inch equalled every one-thousandth of an inch expansion of the conductor A. The scale formed an arc of a circle, having the mirror as its centre.

The connections for the transmission of currents are shown by Fig. 2. A was an ammeter—one of Sir William Thomson's recent Hecto-ampere Balances—and B a voltmeter, reading to a hundredth of a volt, specially constructed by Messrs. Ayrton and Perry on their latest hot-wire method.

C were 15 secondary cells for the production of steady currents, and D was a Lowrie-Hall converter to transform the high-tension currents (2,000 volts) of the electric light station to the low-tension currents (4 volts) required for measurement. The range of variation of frequency was not very great, nor so great as I should have wished. It would have required other converters to have extended the range, for with the converter having the ratio 2,000/4 any reduction in frequency lowered the E.M.F. at the two ends of the conductors, and it was impossible to get the requisite current through the conductors. E was the alternate-current switch, and F that for continuous currents. L was a resistance of platinoid used to equalise the E.M.F. of the accumulators and converter. M was a variable resistance used to adjust the current. The current density was in excess of that adopted in practice, and the currents were so adjusted that they gave a convenient reading on the scale, and they were kept constant during each experiment. All the connections were made of very massive copper.

5. In the preliminary experiments that were made to determine the mode of procedure and the final form of the apparatus, conductors of copper, iron, lead, and platinoid were used, but in the final experiments only iron and copper were employed. Each metal was taken of the same length and of the following forms:—round rod, flat rod, tube, and stranded cable.

* Diagram No. 1. † Diagram No. 2. ‡ The current being higher in this experiment is accounted for as follows: In the other experiments the greater number of alternations produced much greater back E.M.F., which kept the current down. In this experiment, the number of alternations being very low, the effect of self-induction was also low, and the varying resistance used to regulate the current was insufficient, consequently the current given was the lowest obtained. In the direct-current circuit there was a constant resistance besides the varying one, and it was therefore possible to keep that down in the other experiments, but of course in this experiment the steady current was made the same as the alternating.
§ Off scale.

The various dimensions are given in the tables. The temperature was in all cases determined from the elongation of the conductor.

6. The observations were taken sometimes with steady currents and sometimes with alternating currents first. Each kind of current, after being switched on, was kept constant until all expansion ceased, after which the current was instantly changed to the reverse kind, and any change of elongation observed. Each experiment lasted from twenty minutes to half-an-hour. The results are tabulated on the Tables A and B, and some of the experiments plotted as curves on the diagram (Fig. 3). For this latter purpose observations were taken and recorded at every minute. The abscissa is *time* in minutes, and the ordinates elongation in thousandths of an inch.

7. As regards copper, it is very clear that, whether the current were steady or alternating, the effect of heat generated in the conductors was virtually the same; but of the different forms the tube gave the best results, owing, doubtless, to the increased radiating surface.

8. The performance of the iron conductor is very decided. Here we have a large increment of heat, due clearly to reversals of circular magnetisation. Hysteresis evidently plays a most important function, and the conductor in consequence becomes a source of heat, which varies in intensity, not only with the strength of the current, but also with the frequency of the alternations.

9. The difference of behaviour between iron and copper is very marked in the sounds they emit when transmitting alternate currents. Iron vibrates mechanically, and emits loud, powerful sounds, filling the room with a roar, and increasing in intensity with the frequency. The sound of copper is very slight, and only perceptible when the ear is close to the conductor, even with the maximum current. It is only what one would expect from rapid variations in emissivity under such alternations.

This vibration, so marked in iron, has a very important bearing on the durability of the insulating material; for it is difficult to conceive any material that could stand such molecular disturbances without injury for any length of time.

10. This generation of heat in iron conductors leads to the conclusion that the fusing current for small wires would differ considerably between steady and alternate currents. All tables are made on the basis of steady currents. No. 11 iron wire, 116 "mils" (·295 centimetre) in diameter was taken.

Calculating fusing current	.....	122 amperes.
Steady ,,	.....	120 ,,
Alternating ,,	.....	92 ,,

No difference was observed with copper.

11. The general conclusion to be drawn from these experiments is that practically no serious error has been made in the form of conductors so much used for alternating-current systems, and that nothing cheaper or better has been devised than a simple stranded conductor, coated with a suitable insulating coating, and protected outside with lead, or some impervious and strong material.

They do not solve the question of the distribution of current density through the section of the conductor, but they do show that within the range of practice the total flow of energy is the same in copper conductors, whether it be urged by alternate or by steady currents.

ELECTRIC LAUNCHES ON THE THAMES.*

BY PROF. G. FORBES.

This Paper on Electric Launches on the Thames has arisen out of the fact that during the past summer, while I was living down the river at Bray, I was enabled to have the opportunity of keeping one of those electric launches, which have been built by Messrs. Tagg lately, and electrically equipped by Messrs. Immisch. I thought it would be interesting to draw attention to one's experiences in this connection. I speak not only from my own observations, but from those of everyone who has used them on the river, and also the views of a very large number of those who have seen the performances of these boats and watched them, and who are habituated to the river, when I say that there is hardly the slightest doubt that in the course of a very few years the steam launch as a pleasure boat on the River Thames will be entirely abolished.

On the river Thames there are some special peculiarities which make the electric launch peculiarly suitable, and it by

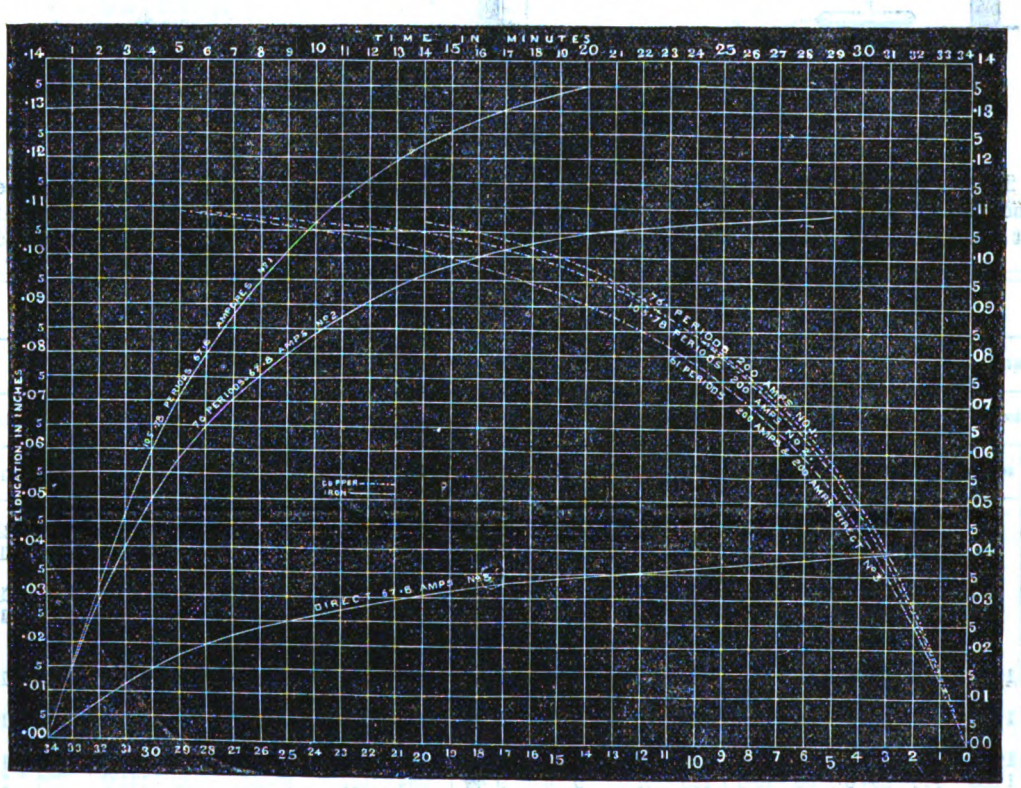

FIG. 3.

* Paper read before the British Association in Section G, Newcastle-on-Tyne, September, 1889.

Digitized by Google

no means follows from what I have said that in other cases the electric launch will be as speedily and universally adopted. Among the points worthy of notice are—in the first place, that launches on the river are required chiefly in summer, when the heat, smoke, smell, oil and dirt of a steam launch are objectionable; and also that, owing to the larger traffic, and to prevent injury to banks and boats which are tied to the banks on the river, it is impossible on the Thames to allow high speeds in launches. Hence a comparatively small supply of storage batteries or accumulators is required for driving the electric launches at the very moderate speeds which are permissible on the river Thames.

It may be also added that on the Thames it is easy to secure a sufficient number of charging stations. At present there are four or five at easy distances apart. Eventually there can be little doubt that the hotels on the river will find it financially a good plan to be lighted electrically, and then this power which they have on the premises can be used during the night for charging the storage batteries of launches.

The house which I occupied was at Bray, just below Maidenhead, and each night I took the launch by myself, towing a boat behind, up to the charging station (which was not a mile away). I left it there to be charged during the night, and by breakfast time the launch was outside ready charged, with a sufficient supply to last me the whole day. I may mention that I never exhausted the complete charge of the batteries in my launch during the whole time. I generally went out shortly after breakfast, spent the whole day on the river, very often coming home at eight o'clock, and afterwards taking it up to the charging station in the evening; and certainly forty miles was not by any means enough to exhaust the supply of electricity on the launch.

The management of the boat is extremely easy, the steering gear and everything about it being perfectly handy. There was no difficulty in crowded locks—going in and bringing up alongside of a lock with the greatest ease.

This launch, which was called the "Delta," is 33ft. in length, has a beam of 6ft., the draught is 15in. forward and 18in. at the stern. She is fitted with 44 cells, weighing in all 2,520lb. She is steered by a wheel in front within reach of the three handles which are required for working her. The first of these handles is used for putting the current on or off, the second one for putting it to half-speed or full-speed, and the third for going ahead or astern. The first one is mechanically moved with the others, so that they cannot be moved without first cutting off the current. Fusible cut-outs are inserted in the circuit, so that if the propeller becomes jammed by weeds or by going aground the motor will not burn up. The speed of revolution of the motor, which is coupled direct to the propeller, is 720 revolutions per minute for full-speed, and 510 revolutions for half-speed. The speed is only between five and six miles an hour for full-speed. This is perhaps the weak point of this launch. I must say there are times when you are going against a strong current in some parts of the stream where a greater speed would be desirable, and it becomes a little tedious creeping up. It is only in a strong stream that one really finds it a little too slow, and for all ordinary purposes it is quite enough. However, the speed might be very advisedly increased a little, I think, by putting in more accumulators, which the launch could easily carry under the floor without overloading. At present the batteries are all under the seats on each side of the boat, and thus the whole of the space in the boat is clear for passengers. My launch could easily have carried twenty with perfect comfort. It is here that the electric launch has a very great advantage over the steam launch; if we consider the size of the launch, and the number of passengers it will hold, the electric launch is really the cheaper of the two.

I spent a day in making tests of the performance of the launch, which may be of a little interest, though they do not go very far. I started from my house one morning at 11:45. I made allowance as I went through the locks for the time that was taken in going through locks and so on, and for other stoppages, and timed everything during the whole way. At one minute past four I was near Hambleton Lock, and began the return journey. Stopping an hour at Medmenham Abbey, I reached Bray again at 7:48 p.m. During all this time the exact measurements of the time were taken, and the result was that in the outward journey up stream the average speed was one mile in 11·3 minutes, and on coming down stream the average speed was one mile in 10·2 minutes. The average of these two is 790ft. per minute. On arrival at home the stern was attached to a spring balance connected by a rod with the shore. The pull at full speed was then measured, and found to be 97lb., which, although it does not accurately represent the pull when the launch is in movement, still it does so with considerably close approximation. This gives us 1·44 horse-power, or 1,074 watts, including electrical losses, slip, and all friction. The pressure of 97lb., over 790ft. per minute, gives that result. The average pressure at the motor terminals during the run was 78 volts, and the average current was 23 amperes, which gives 1,794 watts expenditure. This gives a total efficiency, including all these losses of slip, friction, the end thrust of the propeller, and the electrical losses in the motor, at 60 per cent., which seems to me an extremely fair performance in one of the first types of electric launches which have been constructed by these makers.

I would suggest that there is a very large field open in future—if somebody could be got to organise it, for the delight of those who wish to use these extremely convenient launches on the river—namely, that, in order to supply the enormous demand which will certainly exist after a few years for charging stations, negotiations should be opened by somebody who has the energy to do so with the Thames Conservancy and also with the mill owners—which exist at nearly all the weirs—so as to establish charging stations with water-power at nearly every one of the weirs on the part which launches frequent, and thus to establish what would undoubtedly be a most perfect method of launching in any part of the world.

After a few remarks from Lord Russell, the President (Mr. William Anderson), in proposing a vote of thanks to Prof. Forbes, said there was no doubt a great future for electric launches. One of the Ordnance factories, Waltham Abbey, was under his command, and an electric launch was used there for going about among the network of canals which intersects that factory, in which dangerous operations are carried on, and where it is not desirable to have anything in the shape of fire. The launch answered its purpose perfectly; and it answered in another way incidentally—that is to say, at night, when it is not wanted for cruising about the canals, it is brought alongside an office, and the wires are carried into the office, and the charge in the batteries is used for the electric light during the hour or two that it is required.

TELEPHONE COMMUNICATION BETWEEN LONDON AND PARIS.*

BY W. H. PREECE, F.R.S.

The practicability of speaking by telephone between London and Paris has recently been carefully examined both by the French and the English electricians. The distance between the two places is 275 miles, viz., 74 miles between London and Dover, 21 miles from Dover to Calais, and 180 miles from Calais to Paris. It is very easy to speak over such a distance, if the wires be aerial and of thick copper, but the insertion of underground wires at each end, and of a cable in the middle, place difficulties in the way that have to be surmounted. It is not a question of apparatus—it is solely the distribution of the electrical resistance and capacity of the different portions of the line, and the arrangement and material of the wires.

Speech is already commercially maintained between Paris and Brussels (190 miles), Paris and Lille (158 miles), Paris and Rouen (80 miles), Paris and Havre (135 miles), Paris, Lyons and Marseilles, the latter being a distance of nearly 600 miles; but in all cases they are aerial wires, excepting for a short length (about two miles) of underground work in Paris.

The author has experimented on the cables between Dover and Calais, between Holyhead and Dublin, and between South Wales and Wexford. The conditions to be fulfilled are very

*Paper read before the British Association in Section G, Newcastle-on-Tyne, September, 1889.

Digitized by Google

simple. The circuit must be metallic, the material must be copper, and the product of the resistance of the line, R, and its capacity, K, must not exceed a certain figure. It has been determined roughly by experiment that when

K R =	15,000	speech becomes	impossible.
=	12,500	,, ,,	possible.
=	10,000	,, ,,	good.
=	7,500	,, ,,	very good.
=	5,000	,, ,,	excellent.
=	2,500	or under, speech becomes	perfect.

We have thus a species of Beaufoy's scale applied to telephonic communication.

A circuit approaching as nearly as possible one between London—Paris was made on an artificial cable and it was found to comply with the requirements.

An actual circuit was then made from Worcester, through twenty-seven miles of the London underground system, to Baldock, on the Great Northern Railway, giving similar electrical conditions and with the same result.

It may be considered as absolutely settled that speech is possible between London and Paris.

In the United States speech is maintained between New York and Boston (350 miles), and in many instances to distances exceeding that between London and Paris, but they have not to surmount the difficulties of underground wires at each end, and of a cable in the middle.

The PRESIDENT (Mr. William Anderson) asked why the experiment was not tried direct between London and Paris?

Mr. PREECE said the reason was that all the wires between London and the coast and between Calais and Paris were iron wires, and it was quite impossible to speak over an iron wire to a greater distance than 100 miles. It was only possible to speak at long distances by the aid of copper wire.

Mr. BIGGS asked Mr. Preece whether the highest figure he had given was the absolute limit to which the telephone was possible, or whether, with an alteration of the transmitter and the receiver, it would be possible to have telephony with a higher product than 15,000.

Mr. PREECE replied that 15,000 was the limit now with the present apparatus and with the present means. He did not anticipate any advance in the apparatus; the apparatus itself was nearly as perfect as one could hope it to be, but he did anticipate very great advances in the means of carrying the currents in the form of conductors and in the form of the circuit. They were now quite on the threshold of the subject. The introduction of the telephone and the introduction of alternate-current working in electric lighting were quite opening people's minds to a new field in electricity, and they did not know where they would go to. All that was known was that at the present moment they were on the shore of some unlimited sea, and what might open in the next ten years they could not tell.

SERIES ELECTRICAL TRACTION.*

BY EDWARD MANVILLE, M.I.E.E.

The expenses of horsing a tramway form such a serious proportion of the total working expense that any cheaper effective method of propulsion will naturally be gladly received by the various companies.

Steam and compressed air have been extensively tried, and although in some cases their expense has compared favourably with horsing, the machinery used is so cumbersome, and the nuisance so great, that even companies who have incurred the expense of abandoning horses in favour of steam are seriously meditating the adoption of electricity.

The cable systems have met with considerable success in the United States, and have achieved some measure of success in the United Kingdom; but the conditions under which a cable line can be operated economically are tremendously heavy traffics, such as do not exist in the United Kingdom, but do in the United States, where, as is well known, tram cars are practically the only available street conveyances.

Many leading authorities in tramway administration, who have tested and considered the various methods of tram car propulsion, have of late publicly expressed their confidence in the great suitability and economy of electricity for the purpose.

* Abstract of a Paper read before the British Association at Newcastle-on-Tyne, in Section G, September, 1889.

To distribute electrical power economically from one generating station over distances such as are covered by tramway systems of any extent, it is essential that high-tension currents should be employed, so as to minimise the loss of power in the conductors. Now, if the full tension of such currents were applied to the driving motor on each car, grave difficulties would present themselves in manipulation and in preserving the motor from injury. By the series system, however, it is possible by running the motors in series—as the name indicates—to attain the maximum ease of manipulation together with perfect safety to the motor. This was recognised at an early stage by the late Prof. Fleeming Jenkin and Profs. Ayrton and Perry, and the first electric locomotives ever run in series were used by them in connection with telpherage.

The subject of electrical traction reached such a degree of prominence in this country that early last year steps were taken to demonstrate the practicability of running electric motors for tramcars in series with each other, and an electrical tramway on the series system was equipped and put into operation at Northfleet.

The essential parts of an electrical tramway line in which the motors are run in series are:—An electric generator, producing a current of constant quantity and an electrical pressure varying continually according to the total work being done by the whole of the motors together; the conductor taking the current from the generator to the motors provided with automatic switches of such a character as to enable the continuity of the conductor to be broken as long as the motor is in electrical contact with the open ends of the conductor, and to be closed as soon as the motor, in passing away, ceases to be in contact with the ends of the conductor.

This operation must be performed without disturbing the metallic continuity of the circuit, and without short-circuiting the motor.

The generator used at Northfleet is one of Statter's patent constant-current dynamos, in which type of machine the E.M.F. is varied by the alteration of the position of the brushes on the commutator effected by an electrical regulator. The current, after passing through the regulator, goes to a highly-insulated cable, reaching the whole length of the line. The cable is cut at distances of 21ft. along the line, and the ends of it are led into terminals connected with the opposite faces of a "spring-jack," which is at the same time the automatic switch and contact point from which the current is collected. From the last "spring-jack" at the end of the line, a return cable, with its insulation unbroken, is brought back to the other terminals of the generator, owing to the line at Northfleet being a single track.

The "spring-jack" just referred to consists of a pair of glazed earthenware blocks, 14in. by 3in. by 4in. To each block is attached, by means of a double spiral ring, a gun-metal casting, curved at the ends, but flat in the centre. The springs are of sufficient strength to press the two castings together with a force of 6lbs. Under the car, and for its entire length, is the collector, or "arrow," which consists of two thicknesses of india-rubber belting, each having a broad brass strip rivetted to it for nearly its entire length. The nose of the "arrow" at each end is shod with wrought iron, brought to a knife-edge, so as to easily force its way between the two faces of the "spring-jack," which automatically close after its passage. The conductor on each side of the "arrow" is lapped round one end, and an insulated space is left, slightly greater than the surface of contact of the "spring-jack," near the extreme ends on opposite sides. By these gaps, the passage of the collector, from one "spring-jack" to another, is effected without short-circuiting the motor.

The conductor on each side of the arrow is connected by an insulated cable with the motor carried on the car. On each platform of the car are two strong switches. One of these serves to reverse the direction of the rotation of the armature by altering the connections between the field magnets and the armature, the other regulating the power of the motor by shunting more or less current for the field magnets. Three speeds are provided for, and the stopping of the car is brought about by completely short-circuiting the field magnet, still allowing the current to pass through the armature.

The motors are run at 400 revolutions per minute, delivering at this speed, when the field magnets are fully excited, 15 horse-power on the brake. This slow speed was adopted to do away with intermediate gearing between the motor shaft and the car shaft, which has up to this time been the usual practice.

At Northfleet the motor pinion gears direct with a spur wheel on the car shaft in the ratio of 1—4½. The gearing is double helical, with a view to noisless running, and the practical working of this gear is most satisfactory.

The motors are mounted in a way now generally adopted in the United States, one end being supported by two half bearings on the driving shaft of the car, the other end being suspended by a spiral spring from a stout beam across the car body.

The motors are of the Elwell-Parker type, and the field magnets are connected in series to the armature. The generator is driven by a Robey compound under-type engine of 10 horse-power (nominal), with a locomotive boiler over it.

Digitized by Google

The appearance of the tramway on the road surface is in all respects similar to that of an ordinary tramway, the conduit through which the "arrow" travels, and in which the "spring-jacks" or contact points are situated, being formed beneath one of the running rails. This running rail differs from the ordinary tramway rail, inasmuch as the tread and guard portions consist of two separate and independent rails, having a narrow slot $\frac{7}{8}$in. in width between them, through which the mechanical connections between the "arrow" travelling in the slot and the car body are situated. The rails are supported by means of cast-iron chairs or yokes, to which they are securely bolted. These yokes are placed at intervals of about 4ft., excepting at the rail-joints, where they are closer together, the sides and bottom of the tube between these yokes being formed of Portland cement concrete. The rails are made in 21ft. lengths, corresponding with the distance apart of the "spring-jacks," and at each rail-joint a special chamber is formed, having a convenient removable lid, by means of which access is obtained to the "spring-jacks." The centre of the tube is placed somewhat inside the track, in order that the "arrow," when travelling, shall not be directly underneath the slot, so as to avoid the danger of water from the road surface in wet weather falling directly on the "arrow," and also with a view to protecting the "spring-jack" cheeks themselves in a similar manner. The cable joining the "spring-jacks" is led to an independent 3in. earthenware pipe, running from chamber to chamber, and in this tube also is laid the return cable. Some special construction of points and crossings is necessitated, owing to the junction or crossing of the two tubes underneath the track, which involves a considerable projection of unsupported tongue. The mechanical details of the system were designed by Mr. Joseph Kincaid, and carried out for him under the supervision of Mr. J. S. Waller.

It may be well to point out, in series running, that, owing to the employment of a current of constant value, it is impossible for the most inexperienced car driver to damage his motor by either too rapid starting or by reversing whilst running; indeed, it is a positive advantage when descending a hill to check the speed of the car by altering the field connections so that the armature tends to revolve in the opposite direction to that in which the car is travelling, as the power that would otherwise be lost in braking the car is actually added to that produced by the generator, and thus large systems, with many cars and varying gradients, would appreciably reduce the total power required to be generated and the consequent consumption of coal.

These advantages, combined with the efficiency of distribution as regards the percentage of power lost in the conductors, with, at the same time, but a low difference of potential at the terminals of each individual motor, may be regarded as the main advantages of series running.

There was no discussion, but in reply to the Chairman and Mr. Preece, Mr. MANVILLE said the points occurred on the level of the shank, they would be about on the rail-level. Everything was quite clear down below; there were simply two tubes for the arrow to travel in, and the shank was guided by the point on the rail-level so as to bring the arrow in a proper direction—the same direction as the car was travelling in. The points worked quite automatically, and they were pressed over by a spring in one direction. The maximum gradient was 1 in 32, and it was nearly a quarter of a mile long. They had had no trouble in running up the gradient. The cars carried 26 passengers inside. At Northfleet with two cars the pressure might rise to 500 volts; the average would be from 300 to 350 volts. The effect of reversing the motor in checking the speed of the car going down hill is a very important point. It is not seen perhaps at first sight that in running in parallel it is practically impossible to utilise the brake-power of a car in going down hill. The advantage was only got from it at the few moments when the motor is running at a higher electromotive force than the generator. In series running, where each motor forms an integral part of the circuit, reversing the direction and the rotation of the armature of the motor adds volts to the system which are taken by the generator, and therefore by the steam engine, until the very moment at which the car is stopping. At Northfleet they could actually turn the engine back against the steam when they were going down hill, that is to say, the power developed by the car going down hill passing through the circuit is more than that at the engine at the moment.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 7, 1889.

It would appear that negotiations have recently been entered into between the Postmaster-General, Mr. Wanamaker, and the Western Union Telegraph Company, looking to the establishment of a somewhat novel scheme of postal telegraphs. According to the reports that are now current upon the subject, the Western Union Company will reduce the rates for all short-distance messages, provided that the free delivery system of the Post-office could be used to deliver messages. The cost of delivering messages is one of the heaviest expenses that a telegraph company has to bear, and if economy could be effected in this quarter there could be a reduction in telegraph rates. The idea is that while the Western Union and other telegraph companies should handle the messages as heretofore in the operating rooms at both ends of the line, the Post-office would receive and deliver the messages by means of its present postal force. A further idea is that the department should sell telegraph stamps, thus practically constituting every post-office a telegraph office. This method of co-operation answers in many respects to the system by which the Government now carries on its regular Post-office work. It collects the letters at each end, but it does not own the railroads that transport the mail bags, nor, as a general thing, does it operate on its own account the mail waggons which carry the bags from the post offices to the railway depôts. The idea as proposed seems to have met with not a little favour, and it makes friends on both sides, not only among those who are opposed to Government telegraphs, but those who wish to see the Government giving the people the benefits of cheap telegraphy. There can be no doubt that should such a scheme be adopted, and the contract be entered into with the Western Union Company and the Postal Telegraph Company, in which Mr. Mackay is understood to be interested, it would certainly do much to strengthen the position of those companies against all new comers, and practically give them the monopoly in telegraph business, even if they did not already possess it. So long as the new competitor could come into the field and pick up any business that offered, it would have a fighting chance, but if the business were largely handled through the Post office under contract, and if a new company, in order to bid, had to make enormous preparations for a plant, which failure to obtain the contract would throw on its hands, it is not very likely that capital would be willing to make the effort. In the meantime, while the public is pondering on this new idea, the dispute between the parties as to what will be the rate for strictly Government business remains unsettled, although Dr. Norvin Green has had decidedly the best of it. It is said that the terms on which the Government messages are to be sent in future will not be one mill per word, but two-fifths of a cent per word for night messages and half a cent for day messages.

The fact that the Government of the country has never been sufficiently appreciative of the importance of the telegraph has been very forcibly brought out in the article contributed to the *Century* this month by Dr. J. Emmet O'Brien on "Telegraphing in Battle." Dr. O'Brien was himself one of the members of the United States Military Telegraph Corps, whose good work during the civil war led to the organisation of a large and efficient telegraph force in connection with all the armies of Enrope. Dr. O'Brien's article, which is full of interesting incidents and anecdotes, goes to show that while hundreds and hundreds of operators gave their services to the country and were wounded, imprisoned and killed, not the slightest substantial recognition has ever been taken of their services. The operators who did such a good work and survived have never been awarded pensions or any sort of official rank, nor has any recompense whatever been made to the families of those who gave their lives. Efforts have been made from time to time by certain of them to secure that which is undoubtedly their due, and they have received the warmest support from such men as Grant, Sherman, Sheridan, and McClellan, who well know the value of the telegraph and of the services so unstintingly given, but up to the present time nothing practical has come of the agitation.

In publishing the portrait and biographical sketch, this week, of Mr. J. Frank Sprague, who was at one time a lieutenant in the United States Navy, the *Electrical World* takes occasion to point out the intimacy that has sprung up between the Navy Department and the growing electrical industries of the country. It would seem that owing to the smallness of the American navy since the close of the civil war, and down to a very recent date, the sea has not offered many attractions to the well-trained young graduates from Annapolis, and the consequence is that many of them, availing themselves of the instruction given in electricity, have turned their thoughts and energies to electricity, and, as in the case of Mr. Sprague, have succeeded in making their mark there. Among such men may be also mentioned Dr. Louis Duncan, of Johns Hopkins University, and Mr. Shallenberger, of the Westinghouse Company. In Mr. Sprague's case the rapidity of rise in the profession has been phenomenal, and that gentleman deserves no small amount of credit for the ability and enthusiasm with which he has thrown himself into the work of developing the applications of electrical power. Mr. Sprague was fortunate in receiving the support of the Edison interests, and in enjoying the backing of such a determined and thoroughbred pioneer as Mr. E. H. Johnson, of the Edison Company, and the result has been that Sprague stationary motors are doing their work in enormous numbers everywhere, while Sprague electric railways are to be found in all the progressive States of the Union.

In addition to affecting horses, the electric railway must also, it would seem, have some effect in due time on the shorter of the steam railways. Thus, for example, in conection with the Thomson-Houston road recently put in at Rochester, New York, and running from that city to the summer resort of Ontario Beach, it is stated that the electric railroad has already reduced by one half the patronage of the steam road that it parallels. It can be readily understood that in the summer months, when open cars are used, the electric locomotive must be decidedly preferable to the steam locomotive. It emits neither smoke nor steam, it makes little dust, and throws off no disagreeable soot or small debris of coal, and its motion is remarkably smooth.

We are by no means as far along as you are in the matter of electric launch construction, although, perhaps, we even up when it comes to building "Puritans." The launch "Electron," which has recently made its appearance on the Hudson River, deserves passing mention, however, from the fact that it has made a run of 70 miles, and that it is, so far as can be ascertained, the largest craft of its kind ever built and put into commission. The "Electron" has a hull 36ft. long over all, built of sheet-iron plates. She is decked fore and aft, and has a nice roomy cabin, with a cupola on top at the forward end of the cabin for the pilot house. She is fitted up with a motor from the Electro-Dynamic Company of Philadelphia, which delivers from 15 to 20 horse-power, and which acts directly with a screw, making about a thousand revolutions a minute at maximum speed. The current is furnished by 200 cells of the new motor battery, made by the Electrical Accumulator Company, and known as the 23M type. Each of these accumulators is contained in a vulcanite cell, and consists of 23 plates, which are held apart by thin vulcanite forks. The 200 cells complete weigh four tons. They are arranged about the boat, some in the bottom of the keel, others in the forward deck, and the rest under the seats and along the sides of the cabin. The boat is well trimmed, and the batteries are so disposed as not to infringe in any way upon the space available for passengers. This boat not only made the run down the Hudson River from Newburgh to Newark, but has also gone out through the Narrows to sea as far down the coast as Rockaway Beach.

The American Association for the Advancement of Science has just been holding its meeting at Toronto, under the presidency of Prof. Mendenhall, and a great many Americans have availed themselves of the opportunity to take a trip to Canada, just as they did when the British Association held its memorable meeting in 1884 at Montreal. The meeting is still in session, but will end this week. A few electrical Papers have been presented, among them being one by Prof. H. S. Carhart, of Ann Arbour University, Michigan, on an "Improved Standard Clark Cell, with Low Temperature Coefficient." Prof. Carhart pointed out in his Paper that there were three objections to the Rayleigh form of Clark cell, described by Lord Rayleigh in 1885. One of these was the high and variable temperature coefficient. The second was that it was not constructed in such a way as to keep the mercury apart from the zinc when shaken in transportation. The third defect was the local action taking place by which zinc replaced mercury in the mercury salt, and the zinc became amalgamated, the amalgam even creeping up so as to reach the solder at the copper wire. Prof. Carhart brings forward an interesting form of cell, in which he says that these difficulties are perfectly overcome, while in addition to the low temperature coefficient, great safety in transportation is secured. The coefficient he has obtained is only 0·038 per cent. per degree centigrade, which is somewhat less than one half the coefficient of the Rayleigh form. Almost absolute safety in transportation is also secured by confining the mercury to the bottom of the cell, thus precluding the possibility of its reaching the zinc and short-circuiting the cell, no matter how violently it may be shaken. There is also the advantage of increasing the E.M.F. about 0·35 per cent. above the old form, and there is greater uniformity and constancy. Prof. Carhart also presented a Paper on the "Maxwell Electro-Magnetic Theory of Light," and Prof. Gray brought to the attention of the Association the beautiful new instruments of Sir Wm. Thomson, which have recently been acquired for the Standardising Laboratory of the Ross Polytechnic Institute, at Terre Haute, Indiana.

CORRESPONDENCE.

THE DISTRIBUTION OF ENERGY BY MEANS OF ALTERNATING CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My friend M. Worth has informed me of the series of articles which you were good enough to publish in your journal on the subject of my alternate-current investigations. I was very glad to find that they had attracted your attention, and I thank you for having laid my work before your English readers.

We are, I think, in general agreement, and you rightly remarked that if I indicated solutions of the problem which were scarcely practical it was because I made a great point of proceeding, as far as possible, analytically and indicating all the solutions which naturally presented themselves. I have, however, to reply to two of your observations.

First. You say in your issue of August 9, p. 346:—"It is permissible to question whether, in the absence of direct experimental evidence with modern machines, this decision is as yet wholly justifiable." At the recent Congress of Electricians at Paris, Mr. Gisbert Kapp said that in the latest experiments of Mr. Mordey there was practically no fear of machines employed as motors getting out of synchronism, for in order to do so the work thrown on them must be treble the normal load. May we not invert this proposition and say, all risk of the machines getting out of synchronism is avoided by calling upon them to develop a motive effort equal to only one-third of which they could develop, all things being equal, with a suitable difference of phase. This completely justifies what I said.

On page 399 of your issue of August 23rd you designate as incorrect a proposition so simple that doubtless it is merely a case of misunderstanding. I said that the mean quantity of electricity put into motion *in the same direction* during a second, in a given circuit, by an E.M.F. *variable but always in the same direction*, was proportional to the mean value of the E.M.F. and independent of the coefficient of self-induction of the circuit *at the end of a time long in comparison with the period of the variations of this E.M.F.*

I will restate my proof:—

Let E = the variable E.M.F., always of the same sign.
R = the resistance of the circuit.
L = the coefficient of self-induction of the circuit.
I = the current.
T = the period of the variations of the E.M.F.
t = some length of time.

Digitized by Google

We then have at every instant

$$E = R I + L \frac{d I}{d t},$$

whence

$$\int_0^t E d t = R \int_0^t I \, d t + \int_0^t L \, d I.$$

The quantity E being always of the same sign, the term $\int_0^t E \, d t$ increases indefinitely with the time. The term $\int_0^t L \, d I$ represents, with a constant, the value of the flux of force generated by the passage of a current of intensity I multiplied by the number of times it meets the circuit. Its value cannot increase indefinitely with the time. It is, therefore, a periodic function, of which the period will be evidently equal to the period T of the variations of the E.M.F. when a regular *régime* has had time to become established. Hence, if we are considering a time *t very long in comparison to the period* T, we can neglect the term $\int_0^t L \, d I$, and write,

$$\int_0^t E \, d t = R \int_0^t I \, d t,$$

whence

$$\frac{1}{t} \int_0^t I \, d t = \frac{1}{R t} \int_0^t E \, d t,$$

which demonstrates that what I enunciated is true without any restriction whatsoever.

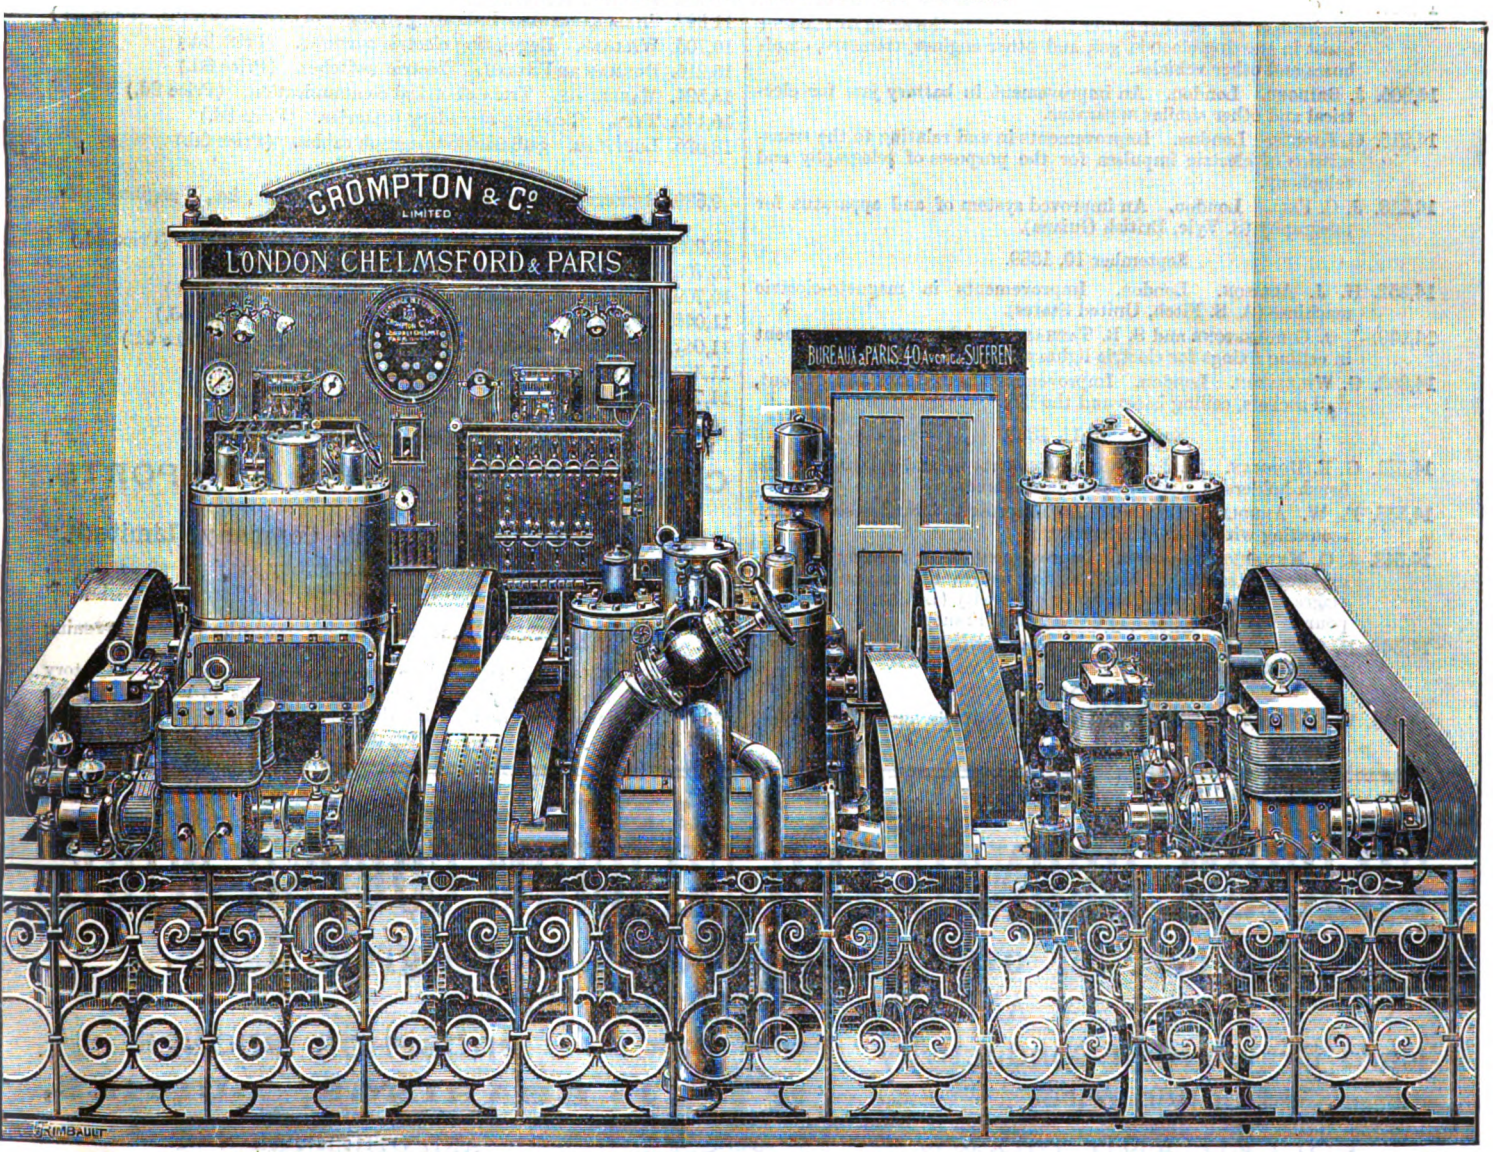
It must be noted, moreover, that there is no difficulty whatever in passing redressed currents round the field-magnets of very powerful dynamos. The self-induction has only the effect of damping the oscillations of the current. It is again a well-known fact that if any difficulty arises in charging accumulators with currents of this description, this difficulty can be overcome by introducing into the circuit a coil of low resistance and high self-induction. This is a fact that I have been able to verify for myself.

I should be greatly obliged if you would submit these few remarks to your readers, and thanking you in anticipation.—Yours, &c.,

M. LEBLANC.

Le Rainey, September 15, 1889.

MESSRS. CROMPTON'S EXHIBIT AT PARIS.



In our issue of June 21st we gave a description of the exhibit of Messrs. Crompton and Co. (Limited), of Chelmsford and London, at the Paris Exhibition. The illustration herewith shows that within the small space of 23ft. by 16ft. Messrs. Crompton have succeeded in placing engines, dynamos, and other machinery of 300 horse-power, sufficient to supply the lighting for the British, American, and portions of the French and Belgian Sections of the Exhibition. This *multum in parvo* will be appreciated by those who are acquainted with the many difficulties to be overcome in successfully disposing of so large a quantity of moving machinery in the comparatively small space at Messrs. Crompton's command. The illustration is from a photograph, and it may be mentioned that the rails in front are about 3ft. in height. On the occasion of a recent visit of President Carnot to the Exhibition, he warmly congratulated Messrs. Crompton on the good use they had made of the limited space allotted to them. The dynamos are of Messrs. Crompton's well-known type, full descriptions of which have appeared in *The Electrician*, and the engines are of the Westinghouse type supplied by Messrs. Alley and Maclellan. The belting was supplied by Messrs. Balderston and Co., of Glasgow.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

September 6, 1889.

14,086. W. C. JOHNSON and S. E. PHILLIPS. London. Improved means for effecting the insulation of electrical transformers, switches, switch-boards, fuses, commutators, and commutator brushes.

14,094. A. A. GOLDSTON. London. An automatic circuit-closing device for series circuits.

September 7, 1889.

14,113. M. IMMISCH. London. Improvements in switches for electrical propulsion purposes.

14,114. M. IMMISCH. London. Improved switch for electrical tramcars.

14,115. C. A. MCEVOY. London. Improvements in primary batteries.

14,116. C. BLANKE. Manchester. Disengaging apparatus actuated by electricity.

14,162. A. DE MERITENS. London. Improvements in treating and rectification or ageing alcohol or alcoholic liquors, or the like, by electricity.

September 9, 1889.

14,169. R. STEENBERG. Newcastle-on-Tyne. Improvements in or connected with telephones.

14,189. W. GIFFARD. Salford. Improvements in arrangements and mechanism for storing power and applying the same to start or assist in starting electric, gas, and other engines, tramcars, omnibuses and other vehicles.

14,206. J. BRIDGER. London. An improvement in battery jars for electrical and other similar apparatus.

14,215. G. FORBES. London. Improvements in and relating to the transmission of electric impulses for the purposes of telegraphy and telephony.

14,218. J. C. FELL. London. An improved system of and apparatus for telegraphy (S. Vyle, British Guiana).

September 10, 1889.

14,232. H. J. ALLISON. London. Improvements in magneto-electric machines (A. S. Fitch, United States).

14,249. J. O. GIRDLESTONE and S. B. TATHAM. London. An improvement in ceiling fixings for electric lights and switches.

14,262. G. WILKINSON. London. Improvements in switches and cut-out, wall sockets, ceiling bases and the like.

September 11, 1889.

14,321. G. E. DORMAN. Stafford. Improvements in and relating to the brush-holders of dynamo-electric machines.

14,333. F. W. ARNOLD. London. An improved incandescence lamp mounting with current interruptor.

14,342. J. C. MEWBURN. London. Improvements in or relating to accumulators or secondary batteries for use in lighting railway carriages and other conveyances by electricity (La Société Anonyme pour le Travail Électrique des Métaux, France).

14,345. R. G. GOATCHER. London. Improvements in the electro-pneumatic actions of organs.

September 12, 1889.

14,366. W. S. BOULT. Birkenhead. Improvements in or relating to arc lamps.

14,374. G. E. DORMAN. Stafford. Improvements in electric arc lamps.

14,377. J. M. BRADFORD. United States. Process of and apparatus for maintaining uniform current in electric lighting circuits.

14,380. G. ALLAN and J. W. BROWN. Liverpool. Improvements in telegraphy and in apparatus therefor.

14,390. G. E. DORMAN. Stafford. Improvements in apparatus for transmitting electric currents to and from the commutators of dynamo-electric machines.

September 13, 1889.

14,448. E. MOROSS. London. An electric chair for nervous and other diseases.

14,453. H. HARPER and R. P. WILSON. London. Improved means for regulating the working of dynamo-electric machines.

14,464. E. BATAULT. London. Improvements in electricity meters. [Date applied for under Patents Act, 1883, Sec. 103, February 15, 1889, being date of application in Switzerland.]

September 14, 1889.

14,485. A. GREENWOOD. Leeds. Improvements in magneto-electric bells or generators.

14,504. W. H. DOUGLAS and T. H. PARKER. Birmingham. An improved instrument for regulating electromotive force.

COMPANIES' MEETINGS & REPORTS.

Halifax and Bermudas Cable Company (Limited).

The statutory general meeting of this Company was held on Thursday, at Winchester House, Old Broad-street, under the presidency of Sir Alexander Armstrong.

The SECRETARY (Mr. James Hay) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, you are aware that this is the statutory meeting of the Company called within four months in accordance with the Act of Parliament as affecting the Companies' Acts. I do not know that I have very much to say to you, only that you will be interested to

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.
PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.

know the progress of business since the incorporation of the Company. We have concluded, as you may be aware, all our arrangements with the Government in a very satisfactory manner, and in our various negotiations with them we have received very fair and equitable treatment. As our future communications with the Government must necessarily be many and frequent, I look forward hopefully, as do also the Board, to receive the same support and cordiality in working which we have hitherto done, and which will tend largely to promote the efficiency of the service in which both the Government and ourselves are so deeply interested. The cable work is now progressing as rapidly as it is in our power to make it, and we look forward hopefully to its being completed at an early period. Nothing that we can do is being left undone to promote the rapidity of the work in hand and its completion. We have appointed the eminent firm of engineers, Messrs. Clark, Ford and Taylor, whose names are a sufficient guarantee that the work will be well and carefully done, and the tests hitherto of the working of the cable have been very satisfactory. The Government have also appointed the principal electrician of the Post Office to supervise the work, in addition to our own engineers, and therefore I think there is sufficient guarantee that nothing will be left undone that can be done to make a good and excellent cable. There have been little unforeseen delays in the manufacture of the cable, which, however, have all been overcome; and, as I have already said, the work is now progressing as rapidly as we can make it. We are now in communication with the Government with respect to the points where the ends of the cable should be landed, both at Halifax and Bermuda. It is necessary that the cable should be laid under the protection of the guns of the fortresses in both places, and that we should be placed in communication with the Governor of Bermuda and the officers commanding the troops at Halifax with that object. Of course until we receive that communication we cannot say exactly where the cable will be landed. The Government have in the island of Bermuda a very admirable system of telegraphy, and there is a private firm of telephony. That will ensure communication right through the island, and be the means of communication with the mainland, and within the reach of everyone. We expect a very extensive traffic from Bermuda. The climate there is remarkably fine in the winter, and the island has hitherto been the resort of Americans to a very considerable extent, but owing to the fact that there has been no telegraphic communication, the island has been left out in the cold. Business men do not like running away from their business, and taking a voyage of three, or perhaps four days, before they can communicate with the mainland, and being cut off from business; but that difficulty will be entirely overcome when we have this cable laid. That necessarily would largely increase our traffic; but, besides that, there is the strategical inportance of Bermuda, which, as you know from the map, is on the same parallel of latitude as Madeira. Owing to the increase in the visitors, I think the traffic will undergo great augmentations. I do not know any island which affords a more desirable residence than Bermuda. It was my fortune when in Her Majesty's Navy to spend a winter there, so I can speak *ex cathedra* of the excellence of the climate and of the geniality and kindness of the natives of the place. They have looked forward with great anxiety and eagerness to this cable being laid, and I think they will be greatly pleased when they find as the result of this meeting that the cable is in process of manufacture. In addition to that, Bermuda also wants this cable communication established with the mainland, as the island will then become a great port of call for steamers. It is also in contemplation by a Canadian Company to erect a weather interpreter on the island, and that will be very important for Europe. Bermuda is 700 or 800 miles from the mainland. It has hitherto been a rendezvous of the fleet, and it possesses a dock, and it is also a very important coaling station as well. That, I take it, will bring a large amount of merchant shipping to the island to report progress and make other communications with Europe. They now run from New York. The steam communication between New York and Bermuda is in fine weather 60 hours—it may be done in three days in fine weather. I look forward hopefully that we shall have a very grand account to make to you at our general meeting after the cable is laid. I think I have given you all the information in my power, but I shall be happy to answer any question.

Replying to questions put by Messrs. Dunlop, Fenwick and Gilkison,

The CHAIRMAN said that 200 knots of the cable were already made. They looked forward to the completion of the cable certainly before the end of the year. The Government would only pay the subsidy when the Company passed the first message through the cable. Meantime the debenture interest would be paid. As soon as possible steps would be taken for giving a market value to the shares. They were to a certain extent bound to complete the cable within a certain time, but they had no doubt they would receive the same consideration from the Government as they had hitherto received if it was not completed by the time. The contractors were bound to deliver the cable in a certain time. As he had said, he expected to have the cable shipped and laid before the end of the year. That would meet their contract with the Government. They had no fear about the contractors not fulfilling their contract by the time specified.

The proceedings then terminated.

NEW COMPANIES REGISTERED.

THE ELECTRIC WIRING AND FITTINGS COMPANY (LIMITED).—Registered by Davidson and Morris, 40 and 42, Queen Victoria-street, E.C., with a capital of £5,000 in £1 shares. Objects: To carry on the business of manufacturers of, and to buy, sell, hire, let and deal in dynamos, mains, batteries, lamps, &c., and generally as electricians and mechanical engineers. There shall not be less than three nor more than five directors. Qualification, being a shareholder. Remuneration to be determined in general meeting.

WILLIAMSON ELECTRICAL AND ENGINEERING COMPANY (LIMITED). Registered by Needham, Parkinson and Slack, 10, York-street, Manchester, with a capital of £5,000 in £10 shares. Objects: To commence, carry on, continue and develop either in New South Wales or elsewhere the business of electrical and general engineers. The regulations of Table A, with slight modifications, apply.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended September 6, 1889, amounted to £3,048.

COMMERCIAL CABLE COMPANY.—A Reuter's telegram from New York says that this company has declared a dividend of 1½ per cent. for the current quarter.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended September 6, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £1,911.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this company for the half-month ending September 15 amounted to £2,034, as compared with £2,490 in the corresponding period last year, a decrease of £456.

In re **ELLIOTT LIVERSEDGE.**—The first meeting of the creditors of this debtor, who carried on business at Huddersfield, was held on Tuesday, the 10th inst. The statement of affairs showed liabilities amounting to £194. 16s. 4d., and assets (after the deduction of £11. 11s. 8d. for preferential creditors) reaching £111. 11s. 10d., leaving a deficiency of £83. 4s. 6d. The cause of failure alleged is a breach of contract. The assets consist of household furniture, upon which a claim has been made under a bill of sale for £30 (alleged to be advanced), executed on the 20th August; and tools, implements, and book debts.

NOTICES OF REMOVAL.—Messrs. Englebert and Co., the well-known lubricant manufacturers, inform us of their removal from their old premises at 70—71, Bishopsgate-street, to more commodious premises at 44—47, Bishopsgate-street Without, E.C.

———Messrs. Rashleigh Phipps and Dawson, now of 185—191, Gray's Inn-road, W.C., announce their approaching removal to larger premises, and that on and after September 30 their address will be 53, Berners-street London, W. The works are at Wells-mews, W.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

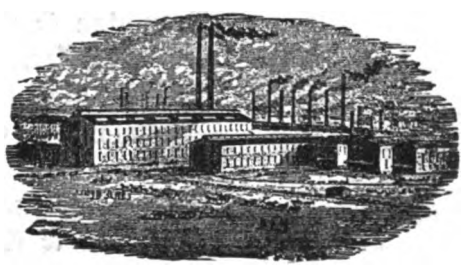
This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 2ft. 6in., varying in thickness from 1-50in. to 1in.



FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Johnson & Phillips.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

MANVILLE & MADGEN, *Managing Directors.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 593.—Vol. XXIII. FRIDAY, SEPTEMBER 27, 1889. Price Fourpence.

NOTES.

A few days since we had the pleasure of inspecting the Electric Lighting Station at Bradford, which, as our readers will be aware, has just been completed by Messrs. Siemens Bros., under a contract with the Corporation of the town. As the first Municipal undertaking of its kind, this station possesses a special interest, and its practical and financial success will doubtless incite many other Municipalities, at present wavering in the balance, to follow suit. For this reason it is, to a certain extent, to be regretted that as a simple low-tension system, this installation, fine as it is in many respects, does not afford an adequate illustration of modern methods of electrical distribution. Under the existing local conditions—by which we refer not only to the topography and the requirements of the town, but also to the opinion maintained by electrical amateurs on the Council—we are, however, prepared to believe that Mr. Shoolbred (the consulting electrician) was, on the whole, justified in recommending a low-tension system pure and simple. We trust that the success of the existing installation of 360 E.H.P. will be sufficient to induce the authorities to see the wisdom of adopting in their contemplated extensions one or other of the available systems by which the radius of distribution can be so widely extended. In our next issue we intend to give a full description of the station as it at present exists.

Since the Bradford Corporation is charging only 5d. per unit the early financial success of their undertaking on the present small scale of operations will in all probability largely depend upon the extent of the day service. It is anticipated, however, that the demand for motors will, before long, become an important feature of the supply. Ultimately, it is hoped that the tramway lines, which are the property of the Corporation, may be worked by electricity, but this is, of course, quite out of the question under the present *régime* of 115 volts.

During the recent visit of the British Association to Newcastle, several of the members visited the station of the Newcastle-upon-Tyne Electric Supply Company, which is now in course of erection. The Company has been fortunate in securing several acres of land admirably situated for the purpose. The North-Eastern Railway runs alongside; at a short distance in one direction is the chief business quarter of the town, whilst in the opposite quarter is one of the most important residential districts. The plant now being erected consists of two Robey compound horizontal engines with automatic expansion gear. Each engine is capable of working at 200 indicated horse-power, and has a 12ft fly-wheel driving by ropes a Mordey alternator for an output of 100,000 watts, running at 430 revolutions per minute. Each alternator has a Victoria exciter driven direct on the shaft and capable of exciting two of the larger machines if required. Owing to the very extensive network of underground telephone lines which Newcastle already possesses, the system of underground mains to be adopted for the alternating currents has required special consideration. A method possessing several novel and interesting features has been worked out by Mr. A. Heaviside (Consulting Electrician to the Company), in conjunction with Mr. Jackson (the Company's Electrician); at a later date we hope to give the details.

Amongst the several Committees of the British Association appointed by Section A is one "On the Magnetisation of Iron," and, as may be readily imagined, its first report was anticipated with a good deal of interest. One naturally looked for a thoroughly competent survey of the present state of knowledge of the subject, in which the many important contributions of recent years would be brought together, and, so far as possible, co-ordinated and generalised. Instead of this we were disappointed and surprised to hear nothing more novel or edifying than a brief historical survey of the discovery of recalescence, and its connection with the magnetic properties of iron. Not a word was said as to the recent researches of Dr. Hopkinson in this particular direction. The report, in fact, cannot be said to present any features of scientific or historical interest which are not already perfectly familiar to the scientific world, and we regard it as quite unworthy of a Committee of the British Association.

To some non-technical journals the laying of a main is apparently synonymous with the lighting of the street, and the operations in the Strand and elsewhere have called forth a good deal of ecstatic writing on the subject of the "new illuminant." "London night-by-night is to be no more; it is to be one continual round of daylight." "The burglars and street brawlers," says another journal, "have had matters their own way far too long. Therefore we hail the prospect of increased electric lighting as a positive boon." Considering that the City Commissioners of Sewers, who alone in the metropolis have seriously taken the question of street-lighting into con-

Digitized by Google

sideration, are in their normal state of adjournment, we are afraid that the "terrible nights of November" will arrive without the "positive boon."

Since writing the above we see that the City Commissioners have returned to the scene of their labours. On Tuesday the debate on the report of the Streets Committee was resumed, and resolved itself without delay into a wrangle as to whether or not the report should be printed and circulated, the proceedings terminating with the inevitable motion of adjournment. For our own part we cannot but concur in the remark of Mr. Deputy BEDFORD, that there has been more than enough consideration already in this matter, and that the City Commissioners bid fair to become "the laughing stock of the whole metropolis."

MEANWHILE, the Vestry of Paddington, which has run the City pretty close in the matter of shilly-shallying, has at length decided to leave electric lighting in their own district entirely to private enterprise. This is, no doubt, the wisest decision they could have come to, and if they had seen things in the same light six months since the practical arrangements would doubtless by this time have been in an advanced stage; as it is, nothing can be done for many months to come.

THE system about to be introduced in the Netherlands telegraph service of classifying telegrams under three heads, namely, "urgent," "ordinary," and "slow," prevails in several continental states, and has been more than once recommended for this country. No good case can be made for such an invidious classification with us, although in some countries its adoption may be regarded as a very desirable reform. The truth is, "urgency" is demanded only where slowness is the rule. In England all telegrams are treated as urgent, and transmitted at a speed which could hardly be accelerated; and the effect of giving undue preference to higher priced messages would be to lower the general average rate of transmission all round. Elsewhere the effect may be to expedite a few messages without materially affecting the general slowness.

THE reduction of telephone rates in France by one-third, consequent upon the acquisition of the service by the French Government, will supply a fresh argument for those who advocate a similar course in respect to the British telephone companies. In the Postmaster-General's Annual Report no particulars are given with regard to the Post Office telephone system, and we may therefore assume that it has not made much progress as a competitor in this line of business. For similar reasons, probably, the particulars under the head of Private Wires also show that the revenue derived from this source increases at a very slow rate indeed. Last year it amounted to the respectable sum of £125,222; but in 1885-6 it was actually greater than it is at present, the rentals having been reduced in 1886-7.

IN an investigation published last year, KUNDT gave a number of results which appeared to indicate the existence of a relation between the velocity of light in metals and their conductivity for electricity and heat, and he pointed out that if this were really the case the velocity of light in a metal would necessarily vary with the temperature. He has recently investigated this point, and finds that the velocity of light in a given metal is inversely proportional to the absolute temperature, which is exactly the same relation which LORENZ, ARNDTSEN and BENOIT have found to exist between the absolute temperature and the electrical conductivity. The results obtained appeared to show that the velocity of light at varying temperatures is, in a given metal, directly proportional to its electrical conductivity.

ON the subject of our recent remarks about ironmongerdom, a correspondent, who appears to have excellent opportunities of judging, informs us that so far from the day having, as we had hoped, quite gone by when any bellhanger or tinker was considered competent to wire a house for electric lighting, the men who are called in to do this kind of work are often not even respectable tinkers, but more commonly gasfitters, than whom no class of artisan can be unfitter for the work he takes in hand, and whose attempts at making a joint are everything that Mr. HEAPHY declares it ought not to be.

SOME valuable results in connection with the treatment of Leclanché cells have recently been arrived at by Herr MÜLLER. He finds that it is a good plan to cover the zinc rod at the point of contact with the air by a piece of India-rubber tubing an inch or so in length. The rate of loss of zinc is often twice as great at or near the surface of the liquid if it is exposed to the air. It is advantageous to amalgamate the zinc, as this prevents the crystals of zinc oxide from adhering to the rod, and thus reducing its effective surface. The solution of sal ammoniac should not contain more than 2 or 3 per cent. of the salt, which is a much weaker solution than it is customary to employ in this country.

THE following somewhat novel demonstration of a well-known theorem has been sent us by an ingenious correspondent, who alleges that he found the document in an omnibus:—

"If a conductor be charged by an excited body, the conductor will repel the body with a force varying inversely as the amount of the charge which the conductor has not received. The total amount of the disturbance will depend partly upon the density of the body and partly upon the resistance of the conductor. If the conductor and the body be carefully separated, it will be found that the body is positive and the conductor negative. Now, let a small disc of copper (or better, of silver) be made to pass from the body to the conductor, and the state of strain will be immediately relieved. If any excess charge should afterwards be found in the exterior coating of the conductor, the conductor may be discharged; but it will usually be found that the amount of charge upon the conductor will be rapidly diminished in the presence of moisture. The cause of this phenomenon may be explained as follows:—Suppose the conductor to be brought into the neighbourhood of a gilded bar; the conductor will be seen to be powerfully attracted. A small disc of copper is then made to rotate rapidly for about a second. After this the conductor will probably part with a portion of the charge, and the moisture will be rapidly absorbed."

DR. LODGE'S article on the Electrical Papers in Section A is unavoidably held over.

Digitized by Google

The Gibraltar-Tangier Cable.—Telegraphic communication across the Straits of Gibraltar is now restored.

University College, Dundee.—The Autumn Session of this College opens on October 7th. For further particulars see our advertisement columns.

The Telephone in Russia.—The Vienna correspondent of the *Standard* says that a telephone line is to be erected between St. Petersburg and Moscow.

The Strike at the Telegraph Construction and Maintenance Works.—The strike of the *employés* of this firm came to an end on Monday, the men's demands being conceded.

Drumcondra.—A splendid palace is now being erected at Drumcondra, a Dublin suburb, for Dr. Walsh, Archbishop of Dublin. The whole building will be illuminated by the electric light.

Electro-Physiology and Therapeutics.—A course of ten weekly lectures and demonstrations on these subjects will be given at the Institute of Medical Electricity, by Dr. Arthur Harries and Mr. Newman Lawrence. The first lecture will be given on October 8th.

The Telephone in Australia.—Telephonic communication is being steadily developed in Australia, the receipts having increased largely in Victoria during the past twelve months. The first long-distance line between Victoria and Geelong is now nearly ready for opening.

Osaka (Japan).—A consular report from Osaka, Japan, draws attention to the introduction of the electric light in that city during the past year. The company is composed exclusively of Japanese, and has a central station fitted with the best American machinery and plant.

Asbestos Reef in Griqualand West.—Recent advices from the Cape state that asbestos of the finest qualities and in large quantities has been found on the land belonging to the Griqualand West Copper Syndicate. Four distinct reefs are reported to have been struck, running four feet wide.

Personal.—On the occasion of Mr. Edward Gimingham (brother of the resident superintendent of the Edison-Swan factory) coming of age, and being appointed to a responsible position in the factory, he was presented with a handsome Wortley writing desk by the officials connected with the works.

The Electric Light in Pearl Fishing.—The project for employing the electric light for facilitating work at the Pearl Banks off the coast of Tinnevelly, has been abandoned by Government, after consulting the Fisheries Departments of England, Scotland, the United States and Western Australia.

Obituary.—The death occurred at an early hour on Thursday last week at Rochfort Tower, South Norwood, of Mr. Cyrus Legge, J.P. for the borough of Croydon. The deceased, who was about 76 years of age, was one of the promoters of the Atlantic Cable, and was connected with many other large undertakings.

Barnsley.—Last Tuesday a meeting was held at Barnsley to consider the action of the local gas company in increasing the price of gas. It was unanimously resolved to present a requisition to the Mayor to convene a public meeting in the Public Hall to consider the desirability of allowing one or more electric lighting companies to enter the town.

Tenders Wanted.—The Rural Sanitary Authority of Wimborne, Dorset, invite tenders for public lighting. Tenders are to be in by October 16th. Particulars can be obtained of Mr. F. H. Tanner, Church-street, Wimborne, Dorset.—Tenders are invited by the Postmaster-General for 8,041 red fir telegraph poles. Tenders are to be in by the 21st October. Particulars of Mr. C. E. Stewart, controller, Telegraph-street, E.C.

University College, London.—The 1889-90 Session of this College commences on October 2nd, and junior and senior courses on electrical technology will be held as usual by Dr. J. A. Fleming. These courses are intended to provide instruction in the subject of applied electricity, and will be supplemented by visits to various central stations and works. The list of subjects dealt with in each class is of a very comprehensive character.

Singular Interruption to a Cable.—An interruption lately occurred upon the cables of the Western and Brazilian Telegraph Company on the coast of Brazil. The cable was repaired on the 17th inst., and it was found to have been broken by a large whale. The cable was embedded in the whale's body for about 50ft. We understand that this is the second instance of a similar character.

Chester.—A special meeting of the Chester Town Council was held on Wednesday last week, for the purpose of considering a recommendation of the Watch Committee that application should be made for a Provisional Order authorising the supply of electricity for public and private purposes by the Corporation. The recommendation was carried unanimously, and the Watch Committee were empowered to take the necessary steps to give effect to the resolution.

Sale by Tender.—The sale is announced of the stock-in-trade, plant and patent rights of Luther Hanson and Company (Limited), of North Bridge Electrical Works, Halifax. There is a considerable stock and plant, and the interest in three patents. Tenders must be sent on or before October 21st to the Official Liquidator, James Duff, Chartered Accountant, Barum House, Halifax. Further particulars will be found in our advertisement columns.

The Measurement of Radiant Energy.—Those of our readers who had not the privilege of hearing the admirable lectures by Mr. Vernon Boys on "Instruments for Measuring Radiant Energy," will be glad to know that they are now appearing in the *Journal* of the Society of Arts, the first lecture having been published on September 20th. Many instruments described are of an electrical character, and the whole subject is treated with great ability and comprehensiveness.

An Electrical Offertory-Box.—"An electrical offertory-box, which rings a bell whenever a button or a piece of tin is deposited in it, is the latest thing 'over the way.' Mr. Edison should adapt his phonograph to the same purpose. Then, when the stingy millionaire deposits his niggardly contribution, the box would announce in clear nasal tones:—'Dives A. Crœsus resides on Fifth Avenue, and has an income of 50,000 dollars. He has given ten cents. Next, please.'"—*Globe.*

Leamington.—A special meeting of the Town Council was held last Monday for the purpose of considering the Lighting Committee's recommendations with regard to the lighting of the Parade by Bray's burners. Mr. Fell, in the course of the discussion, announced that the Electric Lighting Company had intimated that they were prepared to give arc lights with overhead special cables, which would ensure an efficient and cheap light. It was decided that the question of the lighting of the Parade be referred back to the Committee.

Falmouth.—At Falmouth Local Board, on Thursday last week, the Lighting Committee reported that they had considered the applications from certain electric lighting companies. The Committee reported that in their opinion a sub-committee should be at once appointed to watch any Provisional Order that may be applied for having for its object the use of the electric light within the jurisdiction of the Local Board. The report was unanimously adopted, and the Lighting Committee were asked to act in the matter.

The Shaffer Automatic Sprinkler and Fire Alarm.—A demonstration recently took place with a combined electrical fire alarm and automatic sprinkler, which has been devised by Mr. Shaffer. It consists of a small hollow iron box, filled, as usual, with a material which expands under heat, and which in its expansion first closes an electric alarm circuit and next operates a compound lever, which opens the sprinkler, and admits the water through a spreader on to the fire. It is stated to be in extensive use in the United States.

University College of North Wales.—We have received the calendar of this institution for the year 1889-90. The Physical department is under the charge of Prof. Andrew Gray. A special course of experimental work in electricity and magnetism will be begun in October, the course consisting of a series of exercises in (1) Electric and Magnetic Measurements; (2) Practical Applications of Electricity. The new physical and chemical

Digitized by Google

laboratories of the College have an area of 120ft. by 80ft., and contain a room specially devoted to electrical measurements, constructed without iron to insure a uniform magnetic field.

A Portable Extension Ladder for Electric Light Work.—The recent additions to the electric lighting arrangements at the British Museum has necessitated the introduction of a telescopic combined step-ladder platform, which has been constructed by Messrs. J. H. Heathman and Co., of 11, High-street, Bloomsbury. It consists of a double step-ladder mounted upon rubber-tired wheels to pass through a doorway 4ft. wide × 11ft. high, and the base is 6ft. long. By means of a twin rope a step-ladder, with platform sufficiently large for two men to stand upon and provided with guard rails all round, is made to rise to a height of 18ft., while the whole is so light as to be wheeled and turned about by one man.

Royal Victoria Hall.—We are glad to learn that the building of the Morley Memorial College, in connection with the old "Vic.," is rapidly approaching completion. On Thursday last a *soirée* of the past, present, and future students of the College was held in the large museum and library. This large and lofty room is 77ft. long by 34ft. wide, and being lighted from above will be eminently suitable for exhibitions of pictures. The College will contain fifteen class and common rooms of various sizes. The first science lecture at the hall will take place on October 1, when Prof. A. W. Rücker will discourse on "Underground Mountains." Prof. Henry Morley will take the chair, and will address the students on the opening of the College, after which the prizes and certificates won during the last session will be given.

The Definition of "Effective Current."—A Correction.—In the report of the proceedings of the Paris Congress which appeared in our issue of September 6th, a misprint occurred in connection with the definition of "effective current" and effective E.M.F., which it is the more desirable to correct since these terms have now been adopted by the British Association. On p. 454, 2nd column, lines 4 and 9, the expression for the effective current should be written

$$\sqrt{\frac{1}{T}\int_0^T i^2\,dt}.$$

Similarly, in line 10, the effective E.M.F. should be

$$\sqrt{\frac{1}{T}\int_0^T E^2\,dt}.$$

Is Electricity Subject to Duty?—Solicitor Hepburn, of the Treasury Department at Washington, says the *Electrical Review* of New York, has been called upon to decide an interesting question in regard to the introduction into the United States of electricity generated in a foreign country. It seems that an association of gentlemen has established an electrical plant at Niagara Falls on the Canadian side, and propose to extend their wires to Buffalo for purposes of illumination, &c. Before doing so, they desire to know whether the electrical current thus transmitted into the United States would be subject to duty or other tax. It is believed that the solicitor will evade the question by informing the persons interested that it is contrary to the rules of the office to answer hypothetical questions of this character.

Fareham.—A public meeting was held at Fareham last week to consider the question of forming a company to supply electricity in the district. The meeting was addressed at some length by Mr. J. Blake, who said that they could start a company with a capital of £5,000. The works and plant would cost about £4,000, and this would include all the working plant. The annual expenses would be about £600 or £700, whilst he estimated the receipts to be about £1,000. After the matter had been fully debated, papers were passed round the room for those present to fill in, stating the number of shares they were willing to take. Mr. Blake remarked that already £1,000 had been subscribed by personal friends. Several of the papers were then handed to the chairman, and Mr. Blake intimated that in a few days a prospectus would be issued.

The Burton Electric Heater.—The Burton Electric Heater which is now being introduced by the Burton Electric Company, of Richmond, Va., for railroad heating, house warming, cooking, merely consists of a cast-iron case, enclosing some resistance coils, which are covered with dry, powdered clay, for the purpose of absorbing the heat from the wires, and thus preventing them from burning out. The current supplied to the heaters has a potential of 80 volts, and each heater uses about 2½ amperes. It has been found by experiment that such a current raises the temperature of a heater about 200deg. Farenheit. These heaters, once constructed, are expected to be permanent fixtures, requiring no further attention. The moderate rise of temperature is thought to preclude all danger of fire, and it is impossible for the resistance wires to be melted unless the surrounding clay is raised to the melting temperature of the wire.

The Sunbeam Lamp.—The Members and Associates of the British Association had a good opportunity of judging of the excellent effect of "Sunbeam" incandescent lamps for lighting large halls at the *conversaziones* which took place at the recent meeting at Newcastle. The three principal rooms and the vestibule of the museum buildings where they were held were brilliantly illuminated by 300 candle-power Sunbeam lamps, suspended from the ceiling. Considerable interest was excited on the second evening by the exhibition of a Sunbeam lamp of 3,000 candle-power. This, we believe, is by far the largest incandescent lamp ever made, and its effect was very brilliant. We understand that the manufacture of these very large lamps has been rendered possible by recent improvements introduced into the manufacture by Mr. John W. Edmundson, the manager of the Sunbeam Lamp Company's works.

Lectures on the Design of Dynamos.—We have much pleasure in calling attention to the "special course" of lectures announced in our advertisement columns on "The Design and Construction of Dynamo Machines," which will be delivered at the Finsbury Technical College on Monday evenings during the current autumn, commencing on October 7th. If for no other reason than the very low fees charged for the special courses at the College, electrical students have reason to be grateful to the City and Guilds Institute. Prof. Silvanus Thompson, who is going to undertake these lectures, announces that the lectures will be supplemented by exercises in calculation and drawing, to be worked out at home by those attending the class. The syllabus shows that mechanical details of construction, as well as electrical considerations, are prominently treated, and that alternate-current dynamos, motors, and transformers come within the range of the course.

The Finsbury Technical College.—As mentioned in our last issue, the evening classes of the City and Guilds Technical College, Finsbury, reopen on Monday, September 30th. Instruction is given in the Applied Art Department in technical painting, modelling and designing, art metal work, furniture design and cabinet making. Special courses are given for carpenters, plumbers, bricklayers, metal-plate workers, and the building trades generally. Classes are also held for those engaged in electrical, mechanical, and chemical industries. In connection with all the courses of lectures there is a corresponding course of practical instruction in laboratory, workshop, or drawing office. The main object of the College is to impart sound instruction, and to prepare students more for industrial purposes than for examination. The fees vary from 6s. to 30s. for a period of about eight months. Apprentices under 20 are admitted at half fees.

Mr. Edison in London.—Mr. and Mrs. Edison, who have been on a short visit to Sir John Pender, at Foots Cray, visited the Mansion House on Tuesday afternoon, and were entertained at luncheon by the Lord Mayor and the Lady Mayoress. The company also included Lord Brassey, Sir John Pender, Sir James Anderson, Mr. J. S. Forbes, Sir Polydore De Keyser, Colonel and Mrs. Gouraud, the Mayor of Nottingham, and others. Mr. Edison leaves for the United States on Saturday. During his stay Mr. Edison visited the various central stations of the Metropolitan Electric Supply Co., and expressed approval of the arrangements. He also visited the Deptford station of the London Electric Supply Co. On Wednesday, Sir John Pender entertained at dinner at his residence, Foots Cray-place, several

Digitized by Google

scientific gentlemen and others interested in electricity. Mr. Edison was the guest of the evening. Among the company were Lord Crawford, Sir George Elliot, M.P., Sir James Anderson, Mr. Spencer Balfour, M.P., Mr. J. Staats Forbes, Dr. Hopkinson, F.R.S., Mr. F. Leyland, Mr. J. Denison Pender, Mr. John Verity, Mr. Preece, F.R.S., and Mr. S. Z. de Ferranti.

Bourganeuf.—In a recent number of the *Comptes Rendus*, M. Marcel Deprez gives some particulars with regard to the transmission of power installation at Bourganeuf, where, owing to the frequent failure of the waterfall in the town itself, it has been found necessary to obtain the power for driving the electric light machines from a fall at Les Jarrauds, nine miles off. The generator has two armatures connected in series, and mounted on the same spindle. Each ring has a resistance of 2 ohms, and revolves between the poles of a separate field-magnet. The generator is belt-driven by a 130 horse-power turbine running at 150 revolutions. The field-magnets are partly excited by a small auxiliary machine giving 90 volts and 20 amperes. The line, which has a resistance of 23 ohms, is of bare 5 millimetre silicium bronze wire. The motor at Bourganeuf is identical with the generator at Les Jarrauds, and, like it, is independently excited, in this case by the electric lighting machines. At the moment of starting, however, the field is excited by the accumulators at the central station. The dynamos, two in number, are of the Gramme type, giving 110 volts and 250 amperes. In preliminary workshop experiments over an artificial line of 30 and 25 ohms resistance, it was shown that for every 100 horse-power developed by the turbine, at least 60 horse-power was available for lighting purposes, the E.M.F. of the generator being between 3,550 and 3,750 volts.

A Railway Signal Device.—Some trials were recently made on the Nottingham Suburban Railway of an apparatus devised by Mr. W. Andrews, of Nottingham, the primary object of which is to afford means whereby the driver of a locomotive may tell exactly how the signals are at particular points on the railway over which his train is proceeding. For the experiments a mile and a quarter of the suburban line, running from Sherwood Station towards Daybrook, was selected. Parallel with the permanent way there was a zinc-covered wooden rail. By means of a brush attached to the foot-plate of the engine the circuit of two dials placed on the weatherboard of the locomotive was established in turns. One of the dials was in the form of a miniature semaphore signal, the other being similar in appearance to a steam gauge dial, and capable of registering distances from a quarter of a mile up to nine miles. An operator was stationed at each end of the line, and when, acting upon a previously arranged code, the signals were put on or taken off, the fact was at once indicated on the engine. By means of the second dial the distance between various points was also indicated. Mr. Andrews is sanguine that his signalling apparatus would prove of the greatest value in foggy weather when the ordinary signals cannot be seen, as at any point from 200 to 400 yards outside the distance signal the driver would be able to tell at once in what position the particular signal might be, and whether he was at liberty to proceed.

Salford.—A special meeting of the Salford County Borough Council was held on Thursday last week, for the purpose of considering the notice given some time ago by the Manchester House-to-House Electricity Company of their intention to apply for a Provisional Order.—The Mayor moved that the Corporation should apply for a Provisional Order authorising them to supply electricity for public and private purposes within the area of the county borough.—The Town Clerk remarked that if the Council adopted this resolution it was not absolutely necessary that, having got the power, they should carry the scheme into effect. It was his intention to apply to the Manchester House-to-House Electricity Company to withdraw their notice, and the Corporation having taken the necessary steps to apply for a Provisional Order, he hoped they would withdraw it, and so save the expense of Parliamentary proceedings.—Mr. Joseph Corbett asked if the Council were to understand that it was intended to take up the matter of electric lighting in a practical way, or were they to understand that the proposed application by the Corporation was merely to be made for the purpose of hindering electric lighting?—The Mayor said that if the application was granted it would enable the Corporation, as gas makers, to supply electricity if it was thought desirable, and they should also be placed in a position to defend themselves against any outside company which might want to step in.—Mr. J. Snape was of opinion that the proposal made by the Mayor was an advisable one to follow, if only to prevent anybody else stepping in. As to the future of electric lighting, that was a matter for further consideration. After the Corporation had got powers, probably the gas or a special committee would go into the whole matter and report to the Council.—The resolution was carried unanimously.

Calcutta.—In our issue of August 23rd we mentioned that Messrs. Octavius Steel and Co., agents for Crompton and Co. (Limited), had obtained the sanction of the Port Commissioners to light the jetties, the Hooghly pontoon bridge and wharves with the electric light. The following are some additional particulars with regard to the scheme:—The company agree to supply 42 arc lights, each of 2,000 candle-power, at a cost of, for an average of nine hours per night, two annas per light per hour, or Rs.17,293 per annum, as compared with Rs.15,306, the amount now paid for lighting by gas. The company undertake to fix connection boxes at 30 positions within the jetty transit sheds, and on the jetty sheds, these positions to be occupied by movable arc lights placed as required to suit the convenience of such vessels as discharge or take in cargo at night. The vessels lying along the wharves and jetties will be supplied with movable arc lamps, and for the use of the office currents will be supplied to incandescent lamps. Messrs. Octavius Steel and Co. have been allotted two cottahs of land at Pathoreah Ghaut. It is necessary to mention, says *Indian Engineering*, to whom we are indebted for the above details, that the Port Commissioners of Calcutta in adopting these measures are only following in the wake of the Harbour Trusts of Karachi and Rangoon; further, that, as already intimated, Messrs. Octavius Steel and Co. have placed proposals before the P. W. D., Bengal, for lighting the Calcutta *maidans* with electricity. This latter scheme does not appear to meet with that appreciation which would be expected for an acknowledged and needed public improvement in the metropolis of India—particularly when one of the alternate offers involves no additional expenditure, but secures many advantages over the present gas lighting.

The Cost of Street Lighting in New South Wales.—The following information respecting the cost of street lighting by electricity in the municipalities of Tamworth and Young was supplied by the councils of those municipalities, and was read for the information of members of the Municipal Association of New South Wales, at the July meeting, at Sydney:—At Tamworth, the first cost of plant, in which all running machinery is in duplicate, was £3,000. The contractors agreed to work the installation for a period of 12 months for the sum of £470, which did not include interest. The wires covered a distance of about eight miles. There were 73 lanterns, each lantern having two or three 20 candle-power electric lamps. The engines were twelve horse-power nominal. Each dynamo was capable of giving 250 20 candle-power lamps. The incandescent lamps were, in the opinion of the Council, very suitable for street lighting. In addition to the incandescent lamps there are three 2,000 candle-power arc lamps in the main street. At Young the first cost was £7,000; average working expenses, £1,100 for first year, to be paid contractor for providing 1,500 lights if required. Length of wires, 11 miles of main cable for streets, and from thence leading to street lamps and houses about seven miles. Present number of lights and their power, 104 16 candle-power lamps for streets. Capacity of plant, 1,500 16 candle-power lamps. Size of engines, two 75 horse-power, by Fowler, of Leeds. Three 500-light Thomson-Houston alternators and two dynamo exciters. The light was found to be clear and steady. The plant has been examined by the inspector of the Underwriters' Association, and by him pronounced complete, and no exception could be taken to the installation. The light a mile distant from the engine is as good as that near. The annual charge made by the Council to private consumers for use of light was 30s. first light, next four 25s. each, next five 20s. each, next five 15s. each, all others 10s. each.

THE BIRMINGHAM EXHIBITION.

The Exhibition at Bingley Hall is now in a state far nearer completion than when our previous notice was written, though some of the stands remain yet in an unfinished state.

We are sorry to find that the telpher line has been stopped on account of complaints made by neighbouring residents of the noise and vibration which is caused. We understand that efforts are being made to get the train in operation again, and we sincerely hope that the persons on whom the inconvenience falls may be induced to give their consent to its re-starting and running for the short time during which the Exhibition will be open. We must confess to some unpleasant feelings on seeing the telpher locomotive with some rough blocks of wood secured to the lower part, apparently to prevent it from swinging against the supporting posts when going round the curve at the end of the Winter Garden, and the motor covered in by a battered, unpainted tin case. Surely it is worth while to put on a respectable iron case and use a little paint to prevent the public from thinking that Electrical Engineering work is still carried out by scientific enthusiasts, who lack a due regard for appearances, not to say security.

Crompton and Co.—One of the most interesting exhibits in the Hall is that of Messrs. Crompton, who have an electric crane in operation. A description of this crane has already appeared in our columns (*The Electrician*, November 30, 1888), one or two very slight alterations only having been made in the design since then. The chief of these is the replacement of the hand lever, which was employed to throw the travelling motion in and out of gear, by a hand wheel and screw which enables the attendant to leave this motion in gear and give his attention to the hoisting and swinging motion. We were much struck by the ease and precision with which the operator governed the various motions of which the crane is capable, viz., travelling horizontally, swinging round on its centre, and hoisting or lowering. The transition from one motion to another was performed with far greater rapidity and less exertion on the part of the operator than in the case of steam cranes. The crane is constructed to lift 30cwt. at a rate of 80ft. per minute. The reason why an electric crane can be manipulated so completely without loss of time is that the motor can be kept always running. and the changes made entirely by means of friction clutches. This arrangement is made possible by the fact that an electric motor will not "run away," even if the full load is suddenly thrown off, as an ungoverned steam engine would do under the same circumstances. Messrs. Crompton also show on their Stand one of their new "Trade" dynamos for 110 volts and 162 amperes when run at 1,000 revolutions per minute. They are also just getting into operation a 24in. search light. A No. 30 Crompton dynamo, shunt-wound, and capable of running 412 60-watt lamps when driven at 550 revolutions per minute, is fixed in the Machinery Hall, and supplies current to the crane and the lamps in the Swan Company's stand, and, in addition to other lighting, to three motors of Messrs. Crompton's make of the upright magnet single-bearing type, which are driving exhibits at various parts of the hall. One of these, a 3 horse-power motor, drives a large Blackman air propeller, situated at the entrance to the coal mine; a second, a 1 horse-power motor, drives some pen-making machinery at the stand of Messrs. Turnor, pen-makers, of European Works, Birmingham; and the third, also of 1 horse-power, drives a small electro-plating machine and some polishing buffs, &c., at the Stand of Messrs. W. Canning and Co., electro-platers, &c., of Birmingham.

Lacombe and Co.—The exhibit of Messrs. Lacombe and Co. is worthy of notice, though it is not as imposing as many of the others. They show specimens of the different forms of carbons manufactured for various purposes—lamps, batteries, &c. Among other things are two pieces of carbon, used as far back as 1862, with the Holmes apparatus in the Dungeness Lighthouse. The newest forms of fluted carbons are also shown, including two large ones that have been partially used in St. Catherine's Lighthouse this year. These, as also the two historical specimens above mentioned, have been lent to the firm for exhibition by Sir J. N. Douglass, the chief engineer of Trinity House. Nearly all the arc lamps running in the Exhibition are using carbons manufactured by this company. We may also notice an improved form o Leclanché cell (Fig. 1), of which an illustration is given showing the internal arrangements. The zinc rod Z is in the centre, surrounded by the porous pot B; next to this is the depolariser M M, and on the outside the carbon cylinder A. This cover and the porous pot are held in position by the cover and base C C. The terminal N is fixed to a metal collar in contact with the carbon. It is claimed that this arrangement lowers the internal resistance, prevents "creeping," and effects complete depolarisation, because the hydrogen—at every point of the surface of the electrodes—must cross the entire mass of the depolariser before being able to reach the carbon electrode. A further advantage is gained by using a new exciting salt

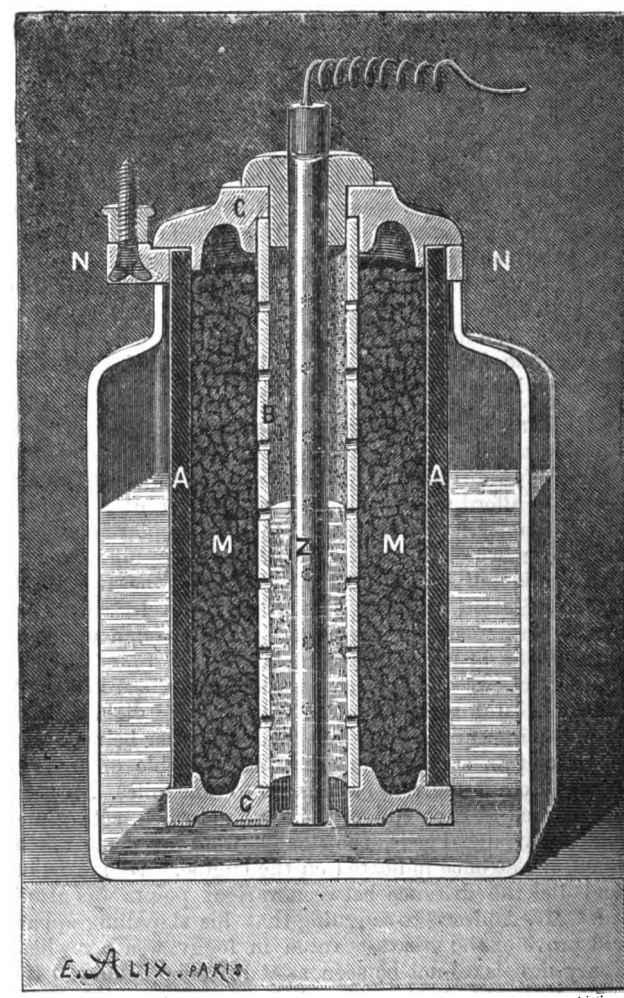

Fig. 1

instead of ordinary sal ammoniac, which prevents the formation of the crystals and allows the zinc to be uniformly consumed throughout the whole of its length.

J. G. Statter and Co.—Messrs. J. G. Statter and Co. (Limited) show one of their mark D C, type A, dynamos, driven by a 4 horse-power Crossley gas engine, and lighting their stand by 22 16 candle-power incandescence lamps and two parallel arcs. The machine gives 40 amperes and 60 volts with a speed of 1,400 revolutions per minute. They also exhibit a 1½ horse-power motor, mark M B, type A, which is of their well-known type, with single upright magnet and pole-pieces bending over to one side. The motor is designed to run at 1,100 revolutions with 60 volts pressure. The motor of the telpher locomotive is also of Messrs. Statter's manufacture, and is of 4 horse-power. In the Machinery Hall Messrs. Statter have one of their constant-current 10 ampere dynamos. The machine is driven from the main countershaft, and is to run four of their "Workshop" type arc lamps in the bay adjoining the Winter Gardens, and also six Bernstein lamps in series with the arcs in the Machinery Hall.

BULLER, JOBSON AND CO.—One of the most striking exhibits at Bingley Hall is undoubtedly that of Messrs. Buller, Jobson and Co., the well-known insulator makers. This exhibit consists of a huge square standard (Fig. 2), covered with some 400 white and brown insulators of all shapes and sizes. The same firm also show iron telegraph poles for use abroad, Jobson's patent driving poles for the rapid erection of telegraph lines, and a large variety of brackets, clips, and insulators for special purposes.

THE NATIONAL TELEPHONE COMPANY.—This company have an interesting and tastefully-arranged display. Their space has been divided into three compartments, the front one being devoted to the display of various forms of telephonic apparatus at present in use, whilst the two back ones are set apart to illustrate a telephonic exchange in operation, and for the purpose of enabling visitors to test the long trunk lines now existing from Birmingham to various towns to the north and south.

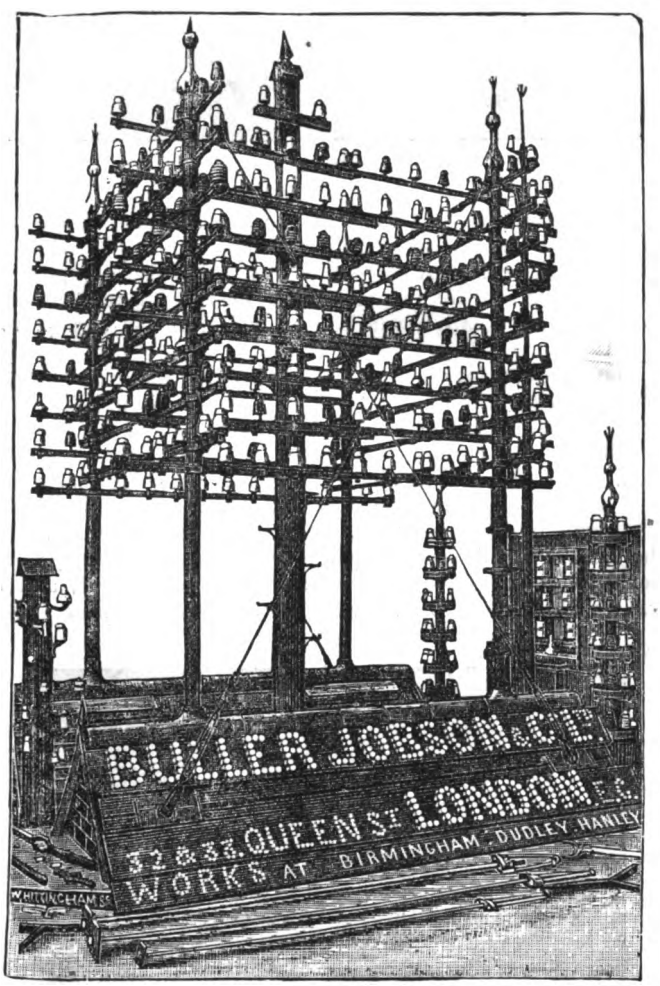

FIG. 2.—Messrs. Buller, Jobson and Co.'s Exhibit.

Taking the exhibit in detail, we noticed at the front one of the usual iron standards, from which run the various lines connecting several stall-holders within the Exhibition, together with trunk and junction lines to the main system. The leading-in wires are led on to a test-board carrying the lightning arrestors. The connecting wires run thence into the telephone exchange before referred to. Here there is a switch-board with a capacity for 80 local lines and for 12 trunk lines (metallic circuits). The switch-board has been specially designed by Mr. Alfred Coleman (general manager), and includes several patents of Messrs. Coleman and Jackson, of which special mention may be made of the trunk line translator, which has an iron shield to prevent induction from adjacent translators or coils, and by an ingenious device is made to act as annunciator, thereby saving four indicators, *i.e.*, one on local wire and one on loop line at each end. An increased efficiency is of course obtained from such a sweeping away of the resistance of otherwise necessary indicators. The adjoining compartment has the appearance of a small drawing-room, and arranged to each settee or chair are pairs of telephones, by means of which any one can hold conversation from various towns. A table set of telephones which can be handed round enables anyone to enter into the conversation. At the front of the stall, where the miscellaneous collection is grouped, we noticed among the samples of apparatus shown portable telephones, an automatic exchange (Mr. Sinclair's patent), several different forms of Messrs. Coleman and Jackson's translators and switching jacks, Messrs. Coleman and Brown's indicators, and numerous forms of call boxes for the use of the public and subscribers, including a recent one designed by Mr. Arthur E. Cotterell, the district manager, which is constructed so as to be contained within one of the usual magneto instruments in the position usually occupied by the battery, for which space is also provided. At the top of the desks are arranged two slits, one marked "pence" and the other "sixpence." On dropping the coin specified through the slit provided, it is carried down a funnel and strikes a special-toned bell, and as the apparatus is attached acoustically with the transmitter through the backboard, the sound emitted by the bell can be easily heard and distinguished by the operator at the exchange. By an ingenious arrangement, if coins of less value are dropped in no signal is given. For the convenience of subscribers special slots are fixed in the front of the box. On a subscriber inserting a special token he is enabled to send a signal to the operator at the exchange, which is clearly recognisable. These slots are two in number, one being for local subscribers and one for trunk.

Great interest was taken in this stall on the opening day by Lord and Lady Randolph Churchill, who entered into a lengthy conversation with Bradford, 123 miles distant.

THERMO-ELECTRIC INVESTIGATIONS.*

BY PROF. H. STROUD.

According to the law of Magnus (1851) no thermo-electromotive force can exist in a circuit consisting of one metal, homogeneous in structure, provided there is no discontinuity of form nor abrupt variation of temperature.

Le Roux (1867) performed a number of experiments, showing that a thermo-electric current is produced in a single metal whenever there is dissymmetry with respect to the point of heating.

Ritter in 1801, and others since, have obtained currents by bringing hot and cold wires in contact, and Franz and Gaugain have pointed out that the effect depends on the state as to oxidation of the surfaces of the metal experimented upon. Some experiments were made by Durham (1871) on the momentary current developed when two platinum wires were brought into contact, the wires being at different temperatures, and he found that the momentary current was proportional to the difference of temperature.

No experiments appear to have been made on the E.M.F. produced when two portions of the same metal are in contact, and the one portion is kept at a high temperature and the other kept at a low temperature. The results of such experiments can be predicted from the thermo-electric diagram, and, conversely, a simple and direct method may thus be obtained for the determination of the Thomson effect. It was with the view of developing this method, which was suggested by the thermo-electric diagram, that the experiments described in this Paper were undertaken.

From the thermo-electric diagram, which represents very clearly the researches, theoretical and experimental, of Sir W. Thomson and of Prof. Tait, we should expect the E.M.F. produced at the point of contact of hot and cold portions of the same metal to be in one direction for those metals for which the Thomson effect is positive, and to be in the opposite direction for those metals for which the Thomson effect is negative;

* A Paper "On the E.M.F. Produced by an Abrupt Variation of Temperature at the Point of Contact of Two Portions of the same Metal," read before the British Association, in Section A, at Newcastle-on-Tyne, September, 1889.

Digitized by Google

copper is a good example of the former, and iron of the latter. In the case of lead, for which Le Roux found that the Thomson effect is inappreciable, we should expect no E M.F. Moreover the E.M.F. should be greater, under similar circumstances, the greater the magnitude of the Thomson effect.

In Fig. 1 we have represented the iron and copper lines of the thermo-electric diagram, with lead as the metal of reference. If copper, kept at a high temperature, indicated by position A in the diagram, is placed in contact with an identical copper conductor, kept at a low temperature, indicated by, say, position B; we should, it seems to me, expect an E.M.F. to be established from hot to cold, seeing that the Thomson effect in copper is positive; or, in other words, since an electric current flowing through a copper conductor, in which there is a gradual fall of temperature, in the direction of the current, has the effect of reducing the differences of temperature, we should expect the contact of hot and cold copper to give rise to an E.M.F. which would be in such a direction as to tend to reduce the difference of temperature, *i.e.*, from hot to cold. Similarly, if two identical iron conductors are placed in contact, the one being kept hot and the other cold, we should expect analogous results; but the direction of the E.M.F. would be opposite as the Thomson effect is negative.

Fig. 1.

The greater the slope of the line representing the metal in the thermo-electric diagram the greater we should expect the E.M.F. to be for a given difference of temperature, for the difference between the thermo-electric powers corresponding to the two temperatures is proportional to the tangent of angle of slope. To find the relation between the E.M.F. and the difference of temperature constitutes part of this investigation: the E.M.F. will be proportional to the difference of temperature in case it is proportional to the difference of the thermo-electric powers corresponding to the two temperatures; for this difference, from the diagram, is represented by difference of temperature × tangent of slope.

Hitherto the experiments made have been chiefly with copper and iron, two typical metals.

From preliminary experiments it was found necessary that the physical condition of the metal experimented upon must be identical throughout the portion of the circuit in which the abrupt difference of temperature was produced, otherwise the thermo-electric E.M.F., due to heterogeneity, quite masked that due to the cause in hand. This condition was satisfied by dividing a tube of the experimental metal, cleaning the surfaces with sand paper, and pressing the similar portions together, a mark on each portion of the tube enabling this to be done very exactly. The surfaces were carefully rubbed down so that good contact was obtained between them when pressed together. The preliminary experiments also showed clearly the necessity of keeping the surfaces in contact free from oxide; the surfaces were therefore cleaned before each experiment.

In the adjoining figure (Fig. 2) is represented the arrangement that has been found suitable. Between the two tubes *a* and *d* were placed the two tubes *b* and *c*, which were pressed together and kept in contact with each other and with the tubes *a* and *d* by means of a spring. *a*, *b*, *c*, *d* were all cut from the same length of tubing, and the ends of *b* and *c* in contact were adjacent portions before cutting. To the ends of the tubes *a* and *d* were soldered the copper or iron wires, which were connected to the galvanometer (a low-resistance Thomson), and in the circuit was included a wire which had a resistance of 0·554 ohms. At the ends of this wire was established, by means of a Leclanché cell and an adjustable high resistance, an E.M.F. of such a magnitude as to balance the thermo-electric E.M.F. The contacts of the tubes *a* and *d* with *b* and *c*, and with the soldered wires were kept at the same temperature by means of a constant current of water flowing through the tubes *a* and *d*, which were connected by an india-rubber tube not shown in the figure.

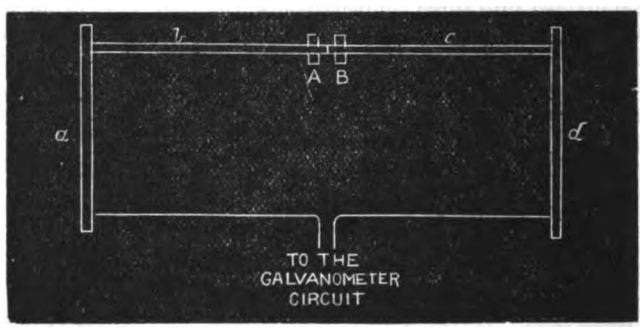

Fig. 2

A and B are two jackets round the adjacent ends of the two tubes *b* and *c*, by means of which the one end can be kept hot and the other cold. A current of steam was used to produce the high temperature and cold water for the low temperature. A and B were usually about half an inch from the ends of the tubes.

The temperatures of the surfaces in contact were approximately determined by means of two iron German-silver junctions, which were placed in small holes drilled as near as possible to the surfaces in contact, the hot junction being bare, while the cold was prevented from touching the metal (and so short-circuiting the E.M.F. to be measured) by means of a small india-rubber tube. It was previously verified that the E.M.F. in this subsidiary temperature circuit was proportional to the difference of temperature of the junctions, and it was found that it = 23 microvolts per degree difference.

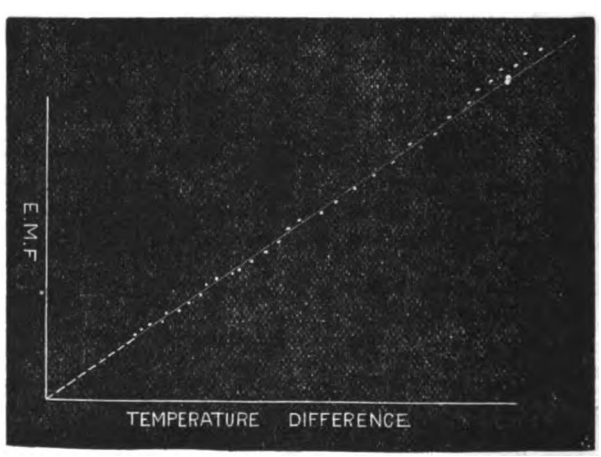

Fig 3

Experimenting with $\frac{3}{8}$″ copper tubes an E.M.F. was established from hot and cold across the junction, showing that the Thomson effect is positive. The magnitude of the E.M.F. was for one experiment, for which the abrupt difference of temperature at the surface in contact was approximately estimated at 30° C., 6·0 microvolts when A was hot and B cold, 5·4 microvolts when A was cold and B hot.

It should be stated that before dividing the tube, of which *b* and *c* formed parts, a similar experiment was made, but no E.M.F. obtained, showing that it is to the discontinuity in the temperature gradient rather than to the steepness of the gradient that the E.M.F. is due.

Digitized by Google

Similar results have been obtained with $\frac{3}{8}$" iron tubes, no E.M.F. being obtainable when the tube is entire, but on division an E.M.F. from cold to hot across the junction, *i.e.*, in the opposite direction to that obtained with the copper tubes, and of far greater magnitude. With a difference of temperature approximately estimated at 30°C the E.M.F. obtained was 74·6 microvolts.

A preliminary experiment has been made, in the case of iron, on the relation between the E.M.F. and the difference of temperature within the range of the above experiments. The method employed was as follows:—When the whole had attained its temperature equilibrium, the steam was stopped while the current of cold water was continued as before; then, while the hot portion was cooling, readings of the two galvanometers were taken alternately, the one galvanometer in the thermo-electric iron German-silver circuit indicating the temperature difference, and the other in the main circuit indicating the E.M.F. From these alternate readings, taken at equal intervals of time, simultaneous readings were deduced by interpolation.

On plotting the curve (Fig. 3) giving the relation between the E.M.F. and the temperature difference it is found to be a straight line, showing that the E.M.F., in the case of iron and within the range of the experiments, is very nearly proportional to the difference of temperature, as indicated by the junctions placed in the manner described.

The following are the numbers from which Fig. 3 was drawn:—

E.M.F.	Temperature Difference.	Ratio.	E.M.F.	Temperature Difference.	Ratio.
304·5	382	·797	114	144	·792
287	352	·816	107·5	137	·785
272	330	·824	101	129	·783
256·5	310	·808	95·5	124	·772
233·5	286	·816	90·5	117	·773
213	267	·798	85·5	110	·777
201	252	·798	81	104	·779
188·5	236	·799	77	99	·778
176·5	222	·795	73	94	·777
165·5	207	·800	69·5	89	·781
155	196	·791	66	84	·786
145	182	·797	62·5	81	·790
136	173	·786	60	77	·779
128	162	·790	57·5	74	·777
120·5	154	·783	54·5	71	·768

The results, so far, of these experiments are:—

(1) The direction of the E.M.F. is opposite in the case of the two typical metals, iron and copper, being from hot to cold across the junction in the case of copper, and in the reverse direction in the case of iron.

(2) The magnitude of the E.M.F. is very much greater for iron than for copper, which corresponds to the much greater slope of the iron line in the thermo-electric diagram.

(3) The magnitude of the E.M.F. is, for the case of iron and within the range of the experiments, proportional to the abrupt difference of temperature on either side of the point of contact.

THE CHENOWETH ELECTRIC CONDUIT.

The following is the report of the Sub-Committee of the Committee on Science and the Arts, constituted by the Franklin Institute of Pennsylvania, to whom the Chenoweth electric conduit was referred for examination. The Sub-Committee consisted of Messrs. Carl Hering, Richard W. Gilpin, Charles H. Richardson and G. Betton Massey:—

"The invention belongs to that class of conduits in which the material of the conduit is packed, while in a plastic condition, around one or more cylindrical cores, which are removed after the plastic material has hardened. The essential part of the invention is the nature of this removable core, which enables it to be withdrawn in long lengths. This core consists of a ribbon of galvanised iron, 1in. wide and of a thickness equal to No. 27 gauge, which is wound spirally, forming a tube. This spiral tube is rendered rigid, either by being wound around a split wooden core or by having paper glued around the outside. The plastic material is packed around these tubes, and after it has set the tube is removed by pulling out this spiral band. When paper has been used to hold the spiral together it readily tears, allowing the band to be removed. When wooden cores have been used, they are first withdrawn, after which the spiral band is readily pulled out.

Among the details of the system are the following:—

When paper is used to unite the spiral into a rigid tube, the ribbon is first wound spirally on a mandrel, then covered with paper, which is glued fast to the outside of this spiral, and the whole covered with a waterproof varnish. The mandrel is then removed, leaving a thin tube, which appears to be quite rigid, and capable of withstanding the pressure due to the packing of the plastic cement of the conduit around it. These are laid in lengths and held in position while the cement for the conduit is packed around them. The ends of the one spiral ribbon are fastened to the beginning of the next by a swivel joint. After a few days, when the cement has hardened, the spiral ribbon is pulled out at one of the manholes, tearing and thus removing the paper around it. It is claimed that long lengths of this spiral tube can be thus removed.

When this spiral tube is wound over a wooden core, this core is made in two semi-cylindrical halves, separated by a thin iron strip. The outside is painted with a mixture of clay, powdered soapstone, and water. These are laid in lengths of 14ft. to 20ft., and after the cement is packed around them the wooden cores are withdrawn, after pulling out the strip of iron separating them. This leaves the spiral tube, which remains until the cement has hardened and is then withdrawn in long lengths.

The inventor claims that continuous lengths of 400ft. of spiral tube can thus be withdrawn. For removing this ribbon, the inventor states that he has a peculiarly constructed reel, by means of which the ribbon can be pulled out, wound up and untwisted in one operation.

For the material used for the conduits, the inventor prefers a mixture of one part of hydraulic cement and two parts of sand. The costs are given by the inventor as follows:—

'The cost of constructing ducts by this method is narrowed down to the winding of the ribbon on the mandrel, the labour of removing the mandrels in the trench, of removing the ribbon from the duct and rewinding the ribbon on the bobbins. And as each part of the core is preserved and used an indefinite number of times, the cost of the core is charged to the cost of the plant. The winding of the ribbon is done on the spot as fast as wanted. The cost of drawing out the ribbon and rewinding on bobbins, using an ingenious device that removes all twists, is about one mill per foot. A duct, 4in. in diameter, made of concrete, in the proportion of one of cement to two of sand, can be made for six cents per foot, including entire cost, exclusive of excavation, manholes and openings.'

The inventor claims that the advantages of the paper-covered tube is convenience, the cost being about the same.

The inventor gives the following comparative costs of materials for three forms of conduits. The estimate is for a conduit of four ducts, 4in. in diameter, 1ft. long. For creosoted wood, six cents per foot per duct; for iron pipe encased in concrete, 18 cents per foot per duct; for his conduit, three cents per foot per duct. This does not include excavation, which is about the same for all. It does not include the cost of handling his removable core.

Your committee have examined samples of these removable cores, and portions of conduits made in this way, and are of the opinion that the invention is simple, ingenious, effective and inexpensive. Furthermore, an invention of an efficient removable core enables monolithic conduits to be made of hydraulic cement, whose properties are already well known. Unlike creosoted wood, it contains no substances which are likely to attack chemically the insulation or the lead armour of cables, and unlike iron it does not corrode. The results, therefore, which can be accomplished by means of this removable core are unquestionably of value.

Your committee recommend the award of the John Scott Legacy Premium and Medal to Alexander Crawford Chenoweth, for his improved method of laying continuous electrical conduits."

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, September 27th.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at the St. James's Hall Restaurant.

TUESDAY, October 1st.

ROYAL VICTORIA HALL.

8:30 p.m. "Underground Mountains." By Prof. A. W. RÜCKER.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

MR. SWINBURNE ON THE DESIGN OF TRANSFORMERS.

It is probably within the mark to say that 90 per cent. of the alternate-current transformers now in use owe their evolution to a process chiefly empirical; one in which calculation has only been employed to modify, and has done but little to forecast experimental results. It has been generally believed, moreover, that high efficiency could be quite easily attained (at least under full load) by any inter-linked combination of copper and iron, and in this belief makers have, as a rule, been content to rest. Mr. SWINBURNE will have done good service if his Paper serves only to call attention to the atrociously bad performance of which some of the transformers exemplified in his Tables are capable. Mr. SWINBURNE is not the first writer, as he also modestly indicates in his opening paragraph, who has furnished formulæ for the design of transformers on scientific lines, but his discussion of the problem is more detailed and in many respects more complete than any of his predecessors. His theoretical investigation results in an equation (unfortunately a cubic) whose solution is intended to yield the most economical value (under actual working conditions) for the dimensions of the core. The following are the quantities in terms of which this value is to be expressed:—The induction in the iron, the frequency, and the resulting loss by hysteresis per cubic centimetre of iron, the current density in the coils, the loss per cubic centimetre in the copper, and the *total* output. It will be at once observed that nothing is set down for the Foucault current losses, and near the close of the Paper the author justifies their neglect in the following sentence (the italics are our own):—

"The loss by Foucault currents has not been taken into account in this Paper, as it can be reduced to any desired extent by laminating or using fine wire; *but the plates must be very thin to make it really negligible.*"

There is, however, some evidence to show that this omission is much more serious than the Author seems to suppose. In a set of experiments in which the conditions were comparable to many of the cases entered in Mr. SWINBURNE's tables (the magnetisation being 12,300 and the frequency 30), it was found by Mr. MORDEY (*Jour. Inst.*, No. 81, p. 621) that with iron plates ·048 centimetre (·012in.) thick the loss in Foucault currents was roughly *three times as great as that due to hysteresis.* These experiments will be found to be in fair agreement with those of EWING and HOPKINSON, from which the eddy currents can be obtained by difference. Mr. SWINBURNE, on the other hand—

Digitized by Google

basing his conclusions upon a formula originally given, we think, by Lord RAYLEIGH—arrives at results which make the eddy current losses less than 10 per cent. of these values. This is very unsatisfactory, and it would seem desirable that the whole question of eddy currents should be more completely thrashed out than has yet been done. It is, however, due to Mr. SWINBURNE to remark that if he had taken the eddy current losses into consideration in his formulæ his general argument would, so far as appears upon the surface, have been considerably strengthened.

From the point of view of the practical designer we have, however, to consider what thickness of iron shall actually be employed, and we do not get much help by being told that the eddy current losses "can be reduced to any extent by laminating the iron," because this is, in fact, an expensive process, and if we are to learn how to make the most economical transformer for given conditions of working, it is certainly of importance to know whether we can use iron costing 3d. per pound (as the author takes it all through), or whether we must pay perhaps twice as much for it.

Passing this by, we note as a singular fact that Mr. SWINBURNE has calculated his tables (with one or two exceptions) upon the basis of a constant current density for all outputs. In the first table the output of different sizes ranges from 2 to 1,000 lamps, but the current density is maintained at 1,000 amperes per square inch throughout. This may be an oversight; or it may possibly be connected with the remark made in an earlier paragraph, that "a dynamo which gets hot is not necessarily inefficient." This is quite true up to a point, but the argument is one which must be handled with due caution. Mr. SWINBURNE proceeds to say a little vaguely that "a large transformer can radiate more heat than a small one, and can thus keep cool, though less efficient." The proposition is perhaps better stated somewhat in the following way:—If two similar transformers (or other machines) of different sizes dissipate energy at the same rate, the larger, having the greater actual surface, will assume a lower temperature, whilst if the rate of dissipation of energy is proportional to the mass, the smaller machine will be the cooler. We need not, however, further consider the actual figures contained in the tables, because, as may be seen in Table IX., and as the author himself admits, the regulation of the secondary E.M.F.—a point, it need hardly be said, of vital importance—is in most cases hopelessly bad. We fear, therefore, that Mr. SWINBURNE's formula will meet with little appreciation amongst practical men unless he can modify it by the introduction of a term to determine the maximum percentage fall of potential in the secondary coil.

In the second part of his Paper the author gives us a series of scale diagrams, showing the proportions of iron and copper in transformers designed on the same basis, but under various conditions as to induction and "time load" (*i.e.*, number of hours per day when full load is on). The frequency is now raised from 33 (the figure at which it stands in the first eight tables) to 80. Foucault-current losses are still disregarded, although it must be remembered that whilst hysteresis increases (at least approximately) as the frequency, the eddy currents increase *as the square* of the frequency. The conclusion arrived at is that—

"The best full lead transformer is bad for short loads, but a short load transformer, though more efficient at short loads, and not much inferior under continuous full load, is a hopelessly bad regulator, besides being too expensive in copper."

A mere inspection of the diagrams is quite sufficient to lead one to the same conclusion (at least as regards the latter part), the copper bearing an extravagantly large ratio to the iron.

Finally, the author propounds a remedy of a somewhat heroic type. This is nothing less than a return to the open magnetic-circuit transformer. The first effect of this modification is obviously to reduce the quantity of iron in which losses by hysteresis (and eddy currents) can take place; but in order to keep down the primary current at no load and to maintain the induction the copper must be still further increased. Unfortunately, at least for purposes of discussion, the mathematical expressions prove unmanageable, and Mr. SWINBURNE recommends the process of working backwards from assumed proportions. The subject is only developed to a very meagre extent, but he tabulates some results (*not* experimental) in which the efficiencies both for full and short loads came out better than with the closed circuit transformer already calculated for the same induction and frequency. In one case the fall of potential is 2·46 per cent., which is a little worse than in the corresponding closed circuit-transformer; and in the second case it stands at 4·35 per cent., which, though bad in itself, is better than the corresponding one.

It is evidently impossible upon the evidence before us to decide whether in general by this method of construction the saving of energy in the iron is or is not an equivalent for the increased loss of energy in the copper *when proper regulation has been provided for.* So far as we can see at present this question of regulation must at the best very much limit the successful application of Mr. SWINBURNE's ingenious proposals. The question also arises whether, after all, there does not exist some quite different and perhaps more entirely satisfactory method of treating the problem of transformer efficiencies under varying loads. We venture to prophesy that some such method will ultimately be found. But meanwhile we must all feel grateful to Mr. SWINBURNE for the immense amount of trouble he has taken in preparing so elaborate a Paper, dealing as it does with a subject of peculiar difficulty and of much practical importance.

THE DESIGN OF TRANSFORMERS.*

BY JAS. SWINBURNE.

(*Concluded from page 495.*)

Leaving these tables, as the induction might be considered too high, and as the loss might also be considered excessive, we may return to our equation:—

$$3\,l\,x^6 + 2\,l\,b\,x^4 - 2\,k\,p\,d^2\,b^2\,x^3 = 6\,k\,p\,d^2\,b^3.$$

The more usual frequency of 80 per second will be taken. The current density d will be taken at 150 amperes per square centimetre, which is about 1,000 per square inch. The primary will be taken at 2,000 volts and 1·5 amperes, and the secondary at 100 and 30. Allowing for double cotton insulation, and assuming the sectional area occupied by a wire to be the square of its over-all diameter, $k = \cdot375$.

To find l, the waste of power per cubic centimetre of iron for any virtual induction, such as 10,000, we may take the loss per cubic centimetre from Prof. Ewing, and multiply by the frequency; this allows a margin for the air spaces among the wires or plates, and comes about right with round wire. It is not likely that the iron used in commercial transformers is nearly so well annealed as Prof. Ewing's specimen, and it is generally handled a good deal in the workshops. A small allowance should also be made for Foucault currents. Some authorities would also make an addition for viscous hysteresis.

The specific resistance of copper is about 1·8 microhms. All the coefficients in the equation can now be replaced by numbers.

In the tables already given the induction was always 14,000;

* Paper read before the British Association in Section G, Newcastle-on Tyne, September, 1889.

Digitized by Google

we will now work out some examples with low and high inductions for various time loads, but always, for ease of comparison, for 50 lamps, or 3,000 watts.

No. 1 (Fig. 2), with virtual induction of 7,000 designed for full load always on, has an efficiency of 95·2, and a drop of E.M.F. of 2·3. The same transformer run at full load for two hours a day, or at half load for eight hours a day, has an efficiency of 74·7. The figure is to scale.

No. 2 (Fig. 3), with same induction, designed for two hours a day, has 81·5 efficiency, and at full load always its efficiency goes up to 92. Its drop is no less than 7·3.

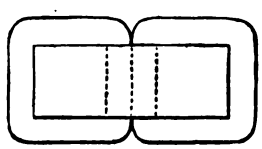
No. 3 (Fig. 4), with virtual induction of 10,600, designed for continuous load, has 95·1 efficiency, and at two hours a day, 72·5; drop 2·2.

No. 4 (Fig. 5), same induction, designed for two hours a day, has 81 efficiency, and 91·5 under continuous load, the drop being 8. No. 5, with induction of 14,000, has efficiencies of 94·6 and 71·2, and drop of 2·3.

No. 5 (Fig. 6), with induction of 14,000, has efficiencies of 94·6 and 71·2, and drop of 2·3.

No. 6 (Fig. 7), with same induction, designed for two hours a day, has 77·5, and 90 per cent. on continuous full load, drop being 9·2.

Fig. 2



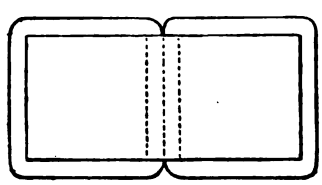


Fig. 3

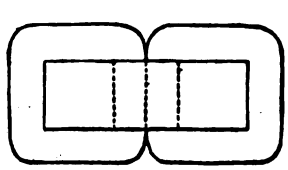
These examples show that a low induction is a little better, but it can hardly pay for the extra cost. The chief point is that the best full load transformer is bad for short loads, but a short load transformer, though more efficient at short loads, and not much inferior under continuous full load, is a hopelessly bad regulator, besides being too expensive in copper.

Fig. 4.



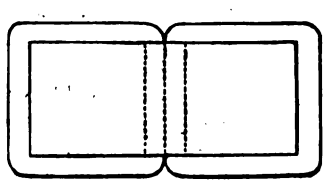


Fig. 5.

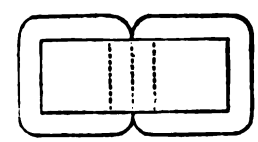
Suppose, instead of a closed iron circuit we use a transformer of the Ruhmkorff coil type. The iron will be less, but the magnetising current will be considerable, especially in small sizes. To reduce this difficulty, I carry the ends of the wire cores out past the cheeks of the coils, and then spread the wires out into a sort of thistle-head or hedgehog. The magnetising current cannot even then be left out of account, as it may be very considerable. The magnetising ampere-turns depend on the dimensions of the transformer, and the size and current density of the primary depend partly on the magnetising current, and these quantities are involved in such a way that a calculation to find the best form for a given case gives three complex and unmanageable simultaneous equations. It is much quicker to find the best form by trial, altering one dimension at a time, as independent variable, till a good result is obtained.

To get the magnetising current, or the primary current at no load, the bushy end is taken as having a hemispherical surface, and the direction of the induction in the air is taken as radial, whereas it really curves round on all sides to the other hemispherical surface. The magnetising current is thus very slightly over-estimated. The primary current is taken as the root of the sum of the squares of the magnetising and the main current. Calling the diameter of the core w, the length of the coil and straight part of the core t, the thickness of winding z, and the radius of the hemisphere y, the magnetising ampere turns per centimetre of iron h, the total excitation needed is

$$h\,(t+2\,y)+\int_{y}\frac{B_{y}\,w^{2}\cdot 64\,dy}{16\,\pi\,y^{2}}.$$

The first term may be neglected.

Fig. 6.



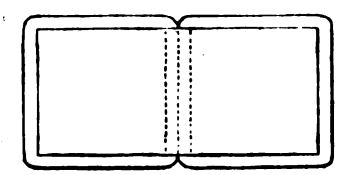


Fig. 7.

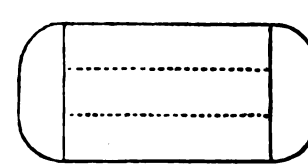
As example, No. 7 (Fig. 8), we may take a medium induction of 10,600, and take w as 5·5, t as 25, and y as 8. At full load, for which this is designed, the efficiency is 96·2; at two hours it is 77·3, and the drop is 2·46. In estimating the efficiency at two hours a day, allowance is made for the loss in the primary when the secondary is open. This is small in power, but it is of considerable importance, as it is always on.

Fig. 8.



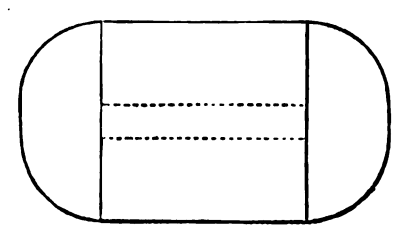


Fig. 9.

No. 8 (Fig. 9) is for short loads. The core is 4 centimetres in diameter, and the ends 10 centimetres radius. Its two hours' efficiencyis 86·6, and at continuous full load it is 95. The primary current density is here taken less to keep down the loss due to the no load magnetising current.

Table XI. shows these results for easy comparison. It will be seen that the last example has at full load almost as high an efficiency as 1 or 3, which were specially designed for full loads. At two hours it is very much superior; but its drop is rather

Digitized by Google

serious, and it takes a lot of copper. No. 7, on the other hand, though designed for constant full load, has nearly as high a light load efficiency as the closed circuit light load transformers, and has a small drop, and has least material of any.

TABLE XI.

No.	B_v	Power.		Efficiency.		Drop.
		Iron.	Copper.	24 hours.	2 hours.

The diagrams show that the closed circuit transformers designed for light loads are absurdities that no one would think of making. It must also be remembered in connection with them that the assumption that the only E.M.F. induced in the coils is due to the core induction is obviously absurd.

Where the copper coils are relatively small, it may be assumed that the electromotive force in each depends only on the iron; but in all the cases given allowance must, in practice, be made for lines of induction which do not pass through the iron, produced by each coil. Obviously it would be best to mix the primary and secondary wires together; but there are great practical objections to this, as the wires are then difficult to insulate properly, and the capacity of the transformer as a condenser may be great enough to involve danger to life.

Probably transformers for very short loads could be made very much better than Nos. 2, 4 or 6, without any iron. In 1882-3, seeing in an electrical text-book that an iron core merely concentrated the lines of induction, without increasing their number, and knowing no better myself, I argued that as there was loss of power in magnetising the iron, a transformer with the wires mixed would do without iron. I made one with a commutator driven by a motor for direct currents. It lighted part of a Swan carbon, but gave a very small output, and the commutator sparked. I also tried an alternating current; but, as a matter of fact, the transformer was very badly designed. Messrs. Gaulard and Gibbs were really first with mixed wires, which is not a point of no importance, even with cored transformers. I took out a patent in 1884, when the fees were reduced, but it is not even worth the reduced cost. It is merely a matter of theoretical interest that with mixed wires, and a lavish expenditure on copper, an efficient short-load transformer might be made. In the transformers we have discussed the coils must be separated, and the primary has to be given fewer turns, and the secondary more, to give the right output.

The loss by Foucault currents has not been taken into account in this Paper, as it can be reduced to any desired extent by laminating or using fine wire; but the plates must be very thin to make it really negligeable.

Take a piece of wire 1 centimetre long, of radius r. The virtual E.M.F. on any elementary layer is $4 B_v r^2 \pi n$, and the resistance of such a layer is $\frac{2\pi r R}{dr}$, where R is the specific resistance of warm iron, say 10 microhms. This gives the power $\frac{2 B_v^2 10^{-16} n^2 \pi r^4}{R}$ in the little piece of wire. There are $\frac{1}{4r^2}$ pieces per cubic centimetre, so the watts per cubic centimetre $= \frac{B_v^2 10^{-16} n^2 \pi r^2}{2R}$. To reduce the Foucault current heating to one-fifth of the hysteresis heating at an induction of 10,000 with 80 periods per second needs wire ·06 centimetre in diameter, which is between Nos. 24 and 23 B.W.G.

The Foucault heating in punchings of sheet iron cannot generally be calculated, but is near enough for our purpose if we take circular punchings like dynamo discs of about the same size. For instance, instead of punchings to suit No. 1, we can take washers of 10 and 20 centimetres internal and external diameters. The power lost in a disc by Foucault currents is $P = \iint \frac{8 B_v^2 10^{-16} n^2 t^2 \pi r \, dt \, dr}{R}$, or $\frac{8}{3R} B^2 10^{-16} n^2 t^2$ per cubic centimetre. To give a Foucault current loss equal to one-fifth of the hysteresis loss, with an induction of 10,000 and a frequency of 80, needs sheet iron ·0225 centimetres, or just over No. 35 B.W.G. Of course there are similar losses in iron-cored dynamos. For the thicknesses of iron in common use, the tables I. to X. are probably not far wrong.

In conclusion, it would seem that, from the point of view of the coal bill at the central station, the system of putting transformers permanently on in houses is hopelessly bad. But the coal bill is not everything. The cost of electrical energy does not vary as the coal burned. The house transformer system has also the disadvantage of variations of secondary E.M.F.

Assuming the private transformer system to be necessary, the open circuit transformer, of the kind I have now the honour of explaining, is better for such sizes as 50 lights. If larger sizes are needed the hedgehog kind easily distances the closed circuit; for its drawback is its large magnetising current, and the excitation is less in proportion as the transformer is increased. In all cases a large transformer is more efficient than a small one; its percentage loss decreases faster than the dimensions increase, but the dimensions increase very slowly with the output, so that it takes a very large transformer indeed to get an efficiency of 98 per cent., namely, about 50,000 watts.

If the figures for loss in iron here taken are very low, as seems probable, the arguments in favour of this form of open circuit transformer are very much strengthened. The loss in iron also depends on the frequency, so the higher the frequency the better these transformers are in comparison. It is curious to note that this appears to be a step backwards according to most people's ideas, and that it is also a step towards the original practice of the pioneers of transformer work—Messrs. Gaulard and Gibbs.

DISCUSSION.

Prof. GEORGE FORBES said there were some few points in Mr. Swinburne's Paper to which he would like to draw attention. He was glad Mr. Swinburne had drawn attention to the fact that such very bad transformers were being made by some people at the present time, and also to the fact that since many of the modern transformers have very large loss from hysteresis, it would be much wiser, as Lord Rayleigh pointed out in the *Philosophical Magazine* a few years ago, to have open-circuit transformers to prevent hysteresis from being injurious. He thought Mr. Swinburne was mistaken as to the figures that had been given as to efficiency being so very incorrect. The transformers that Dr. Hopkinson examined of Gaulard and Gibbs, even in those old days when certainly they were not in the most efficient condition possible, were very high indeed; and those he (Prof. Forbes) had examined himself by calorimetric methods had been higher than the figures given by Mr. Swinburne.

Prof. EWING said it had occurred to him that the essence of his (Mr. Swinburne's) conception lay in this—that in the magnetic circuit of a transformer they might on the one hand have the circuiting of the system wholly of iron, a substance having exceeding permeability, but at the same time it is open to the objection that when a magetic circuit is formed there is a certain dissipation of energy through hysteresis. On the other hand they might have the magnetic circuit consisting more or less of air, a substance having little permeability, but also possessing the advantage of having a cycle where there is no dissipation from hysteresis. Mr. Swinburne's suggestion of the hedgehog appeared to him to mix those two—to have the central part iron and then air to complete the circuit. It seemed to him probable that a better result would be achieved by simply reducing the quantity of iron in an iron circuit; but one must bear in mind that the dissipation of energy through hysteresis in iron becomes very much less in proportion to the induction when the induction is higher—that is to say, the iron becomes, so to speak, more nearly elastic as regards its changes of magnetisation.

Prof. S. P. THOMPSON said he did not agree with Prof. Ewing's last remark because, unfortunately, though it might be proved that one got better elasticity with the higher magnetisation, one was also doing so much work on the iron *in toto* that the iron would get

Digitized by Google

very hot unless it had an adequate surface, but it could not have the adequate surface with the small quantity Prof. Ewing supposed. The real point of Mr. Swinburne's Paper seemed to him (Prof. Thompson) to be that he had introduced into the magnetic circuit of a transformer a certain portion of air, and gained thereby. Perhaps it was better to explain it by analogy. At one time it was thought well to regulate alternate-current systems by the introduction of resistance; now it has been found better to regulate alternate-current systems by the introduction of reaction coils, which do not dissipate energy as plain resistance would. If they wanted to regulate the action of the transformer by acting on the iron part, or rather on the magnetic part, as distinct from the electric part of it, they could do it by increasing the magnetic resistance by thinning the iron, or they could do it, not by thinning the iron, but by cutting out a gap and leaving the air. In the one case, thinning the iron would leave them in the presence of the iron which dissipates energy; in the other case, introducing the air-gap would leave them in the presence of the air which did not waste the energy, being magnetic and perfectly elastic. The gain is similar to that of putting in a reaction coil as against a resistance coil in the electric circuit. He was not sure that he could agree with Mr. Swinburne's way of constructing this coil. What was the real gain of spreading out the heads of a core into a hedgehog, as it was called? He not only believed that the arrangement of the iron wires when spread out in that way added to the difficulty of the construction, but he was not sure that it did not add to the risks. He would much rather see a plain cylindrical coil of wire that had to be opened out in the usual way. Mr. Swinburne did not say how long his core was. Of course the question how far it induced magnetic resistance depended upon the length of the core between the two wires.

Mr. PREECE said he had very few remarks to make, except remarks of praise. He thought that was the kind of Papers they wanted. In the present day they were jumping by leaps and bounds, and improving all their systems of distribution particularly and all their systems of apparatus very often indeed; and when they found men deliberately setting to work and studying questions with the experience and the mathematical knowledge, and with the care of Mr. Swinburne—why, they could only hail such papers with pleasure. There was one point Mr. Swinburne had not touched upon. That gentleman had alluded to the fact that in transformers there was an immense amount of waste when the instruments were lying idle. There was no doubt there was an immense amount of waste. The diagrams of the working of the central system in London show that during the daytime there is an immense amount of power gone—really lost in heat. At the present moment experiments were being made, and people were trying to devise switches by which the transformers shall be switched off during the day and the users of light shall only switch the transformers on when they are wanted at night. Why it was not done he did not know—there might be some reason unknown to him—but he knew that some of the large companies were working in that direction.

Mr. SWINBURNE said Prof. Forbes had pointed out that the old Gaulard and Gibbs transformers gave very high efficiency—he had forgotten what the figure was, but he thought Dr. Hopkinson had found something like 88 per cent., and on the whole that was rather a confirmation of his Paper, because they were open-circuit transformers, and they were not the best designed, being generally rather too long. It was also mentioned, as had been mentioned before, that open circuits were more efficient. He had the idea that the ground on which they were mentioned before was that if you had the open circuit the loss per cubic centimetre of iron at a given induction was less, owing to the free magnetism at the end of the core. He did not know whether he was quite right in saying that or not. Prof. Ewing said the iron ought to be reduced to a higher induction. In the Paper he had taken several inductions. The high induction produced rather a low efficiency. He did not quite follow Prof. Ewing's figures, for the losses per cubic centimetre were taken from the one case in his classical Paper, in which what Prof. Ewing called the graded cycles were taken. Prof. Thompson said he did not quite follow the advantage of spreading out the ends, or hedgehogging. He (Mr. Swinburne) did not like to use the term "magnetic resistance," but perhaps he might be allowed to do so. Hedgehogging the ends made the magnetic resistance of the air smaller. The magnetising current was so large that at full load the loss in the primary was something enormous—that was why it had to be so large—and even at no load the loss in the primary came to something very considerable. He thanked Mr. Preece for his kindly remarks. What that gentleman had said about the great loss shown in load-diagrams at stations to a certain extent contradicted Prof. Forbes's experiments as to the high efficiency of transformers.

Prof. FORBES: I did not speak about bad transformers; it was in good transformers I found good efficiency.

Mr. SWINBURNE: I can only say, then, that most central stations must use very bad transformers, in which Prof. Forbes will, perhaps, agree with me.

ON MAGNETIC VISCOSITY IN IRON.*

BY J. A. EWING, B.SC., F.R.S.

When any change is made to take place in the magnetic force acting on a piece of soft (annealed) iron, a considerable time elapses before the resulting change in the magnetism of the piece is complete. The sluggishness which soft iron exhibits in assuming its full magnetism when a magnetic force is imposed upon it was referred to as follows in the account which I wrote, some years ago, of experiments on the magnetic qualities of iron:—†

"Some evidence was given that, in addition to much static hysteresis, there is a small amount of viscous lagging in the changes of magnetism which follow changes of magnetising force. I repeatedly observed that when the magnetising current was applied to long wires of soft iron, either gradually or with more or less suddenness, there was a distinct creeping up of the magnetometer deflection after the current had attained a steady value, as measured by the deflection of the galvanometer through which it passed. This action was sometimes so considerable as to oblige me to wait for some minutes before taking the magnetometer reading."

In his Paper "On the Behaviour of Iron and Steel under the Operation of Feeble Magnetic Forces,"‡ Lord Rayleigh has remarked on the same phenomenon in soft iron. In his experiments the relation of the magnetic force to the resulting magnetisation of the specimen was studied by means of a magnetometer furnished with a "compensating coil," through which the magnetising current passed, and which was so placed that its action on the needle of the magnetometer balanced the action of the iron, giving no deflection. When very feeble magnetic forces were applied to hard iron or to steel, he found that a perfect balance might be obtained by adjusting the position of the compensating coil, and so established the fact that the susceptibility to small magnetic forces, or to small changes of force, is a definite quantity, which is independent of the amount of the small change of force. He observes that with hard iron and steel the compensating coil might be set so that neither at the moment of closing the circuit of the magnetising current nor afterwards was there any deflection of the magnetometer, which means that (so far as the magnetometer can decide) the metal assumes its magnetic state instantaneously. He goes on to say that soft iron shows much more complicated effects:—"When the coil was so placed as to reduce as much as possible the instantaneous effect, there ensued a drift of the magnetometer needle . . . in such a direction as to indicate a continued increase of magnetisation. Precisely opposite effects followed the withdrawal of the magnetising force. The settling down of the iron into a new magnetic state is thus shown to be far from instantaneous. On account of the complication caused by the free swings of the needle, good observations on the drift could not be obtained with this apparatus, but it was evident that whilst most of the anomalous action was over in 3 or 4 seconds, the final magnetic state was not attained until after about 15 or 20 seconds." Lord Rayleigh then cites my observation, quoted above.

In the following experiments, Lord Rayleigh's method of the compensating coil has been made use of for the purpose of examining in some detail this "drift," or "creeping," or quasi-viscous change of magnetism which follows any change in the magnetic force acting on soft iron.

The magnetometer was a light Thomson mirror directed by the horizontal component of the earth's field, and having a free period of double swing amounting to nearly 1½ seconds. The specimen of iron used in the greater number of the experiments was a straight piece of thick wire 0·404 centimetre in diameter and 39·6 centimetres long, over which was slipped a tube with a magnetising solenoid wound upon it. The wire was set in a verticle position, magnetically west of the magnetometer, with its top end on a level with the mirror, and generally 6 centi-

Digitized by Google

metres distant from it. The compensating coil was wound on a wooden frame, which could be moved along a "geometric slide" towards or from the magnetometer in the east-west line through the mirror, for the purpose of balancing the magnetic effect of the iron. In some of the experiments another compensating coil was used to balance the effect on the magnetometer of the magnetising solenoid, but generally the simpler plan was followed of including the effect of the solenoid in the determination of the compensating coil's action on the magnetometer.

To prevent the vertical component of the earth's field from acting on the iron, a second magnetising solenoid was wound over the first, and a constant current of the proper strength to neutralise the earth's field was maintained in it without interruption. The main magnetising current was regulated by having in its circuit a box of resistance coils, and also the liquid slide described in my former Paper.* This allowed the magnetic force to be changed either suddenly or gradually, and the slide also allowed the method of demagnetising by numerous reversals of a continuously diminishing magnetic force to be resorted to whenever it was desired to reduce the iron to a magnetically neutral state.

To soften the wire it was heated to redness by being slowly drawn through a Bunsen flame. After it was put in place the method of reversals was applied to extract a small amount of magnetism which it had acquired in being handled. In the experiments which I shall first describe the effects of very feeble magnetic force were examined by making and breaking the circuit of the magnetising solenoid while the current was adjusted to produce a force of less than 0·1 C.-G.-S. It was found that the *immediate* effect of each make and break could be balanced very exactly by adjusting the position of the compensating coil, and so long as the magnetising force was considerably less than 0·1 C.-G.-S. the distance at which the coil had to be set to give this balance was as nearly as possible independent of the value of the force, and was the same for "break" as for "make." The position of the coil was adjusted so that at the instant when the magnetising current was set up by pressing down a contact key, there was no sudden deflection of the magnetometer mirror to either side. When the compensation was right the spot of light simply began to drift slowly towards the side corresponding to increase of magnetism; when there was over-compensation, the spot of light gave a quiver to the opposite side before beginning to drift, and the position of the coil was adjusted by drawing it back little by little until the quiver on pressing down the key disappeared. The amount of magnetism that was balanced was afterwards measured by removing the iron, but leaving the magnetising solenoid and the compensating coil in place, and observing the deflection of the magnetometer when the same current was passed through the empty solenoid and the compensating coil. This determined the immediate magnetic effect of the magnetising current on the iron, and the subsequent creeping up of the magnetism was of course determined by observing the drifting of the magnetometer needle which had ensued after applying the current while the iron was in its place.

In the following experiment a current of 21 on the arbitrary galvanometer scale (equivalent in this case to a magnetising force of 0·044 C.-G.-S.) was made, after the wire had been completely demagnetised, and after the compensating coil had been adjusted to balance the immediate effect. Magnetometer readings were taken 5 seconds and 60 seconds after "make;" and at 60 seconds the current was broken, and magnetometer readings were taken 5 seconds and 60 seconds after "break." The immediate effect (balanced by the compensating coil) was equivalent to twenty-five divisions of the magnetometer scale :—

Time after "make."	Magnetometer.	Time after "break."	Magnetometer.
0	0	0	13
5″	8	5″	5
60″	13	60″	0

* *Loc. cit.*, § 18, p. 537.

Adding to these the equivalent of the compensating coil, we see that just after the immediate magnetising force was suddenly applied, the value of the magnetism was 25, which increased after 5 seconds to 33, and after 1 minute to 38; and that when the magnetising force was suddenly withdrawn, there was at first a residual magnetism of 13, which fell to 5 in 5 seconds, and disappeared altogether in less than 1 minute.

Next a current 41 (producing a magnetising force of 0·084 C.-G.-S.) was made and broken in the same way. The compensating coil scarcely required to be moved from its former position, and its equivalent on the magnetometer was now 48. The column headed "total" gives the sum of the magnetometer reading, and the part balanced by the compensating coil.

Time after "make."	Magnetometer.		Time after "break."	Magnetometer.
	Observed.	Total.		
0	0	48	0	31
5″	20	68	5″	13
60″	31	79	60″	4

Here, out of the whole original residue of 31 a small part refused to disappear after the lapse of a minute, and it is probable that with this magnetising force some of the residual magnetism is permanent.

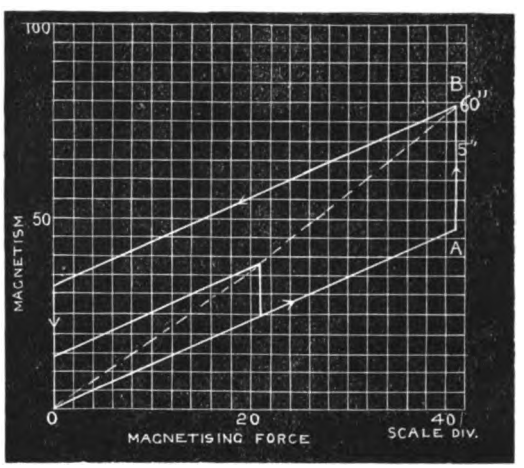

FIG. 1.

The above results are shown in Fig. 1, where the arrows indicate the sequence of magnetic changes. One scale division of the magnetometer is here equivalent to 0·0177 C.-G.-S. units of $\mathfrak{J}$ (intensity of magnetism). The magnetic force due to the solenoid may be taken as approximately equal to the whole magnetic force (although the rod was barely 100 diameters long, this length should be sufficient to approximate to endlessness when one is dealing with very low values of magnetic susceptibility). On this assumption, one scale division of the galvanometer is equivalent to 0·0021 of $\mathfrak{H}$; the initial instantaneous susceptibility, that is, the gradient $d\mathfrak{J}/d\mathfrak{H}$, is 9·9, and the initial instantaneous permeability ($d\mathfrak{B}/d\mathfrak{H}$) is 125. This value has been confirmed by a number of independent observations made with the same piece of annealed wire, and with another piece cut from the same hank and also annealed. Taking the magnetism acquired after 1 minute, the initial susceptibility as regards that is about 15.

Precisely similar results have been obtained by reversing feeble magnetic forces. So long as the forces are very small, the compensation for "reverse" is the same as for "make" and for "break," and the creeping of the magnetism in any given time after make, break, or reverse is nearly proportional to the amount of the preceding change of magnetising force.

In the following experiments the magnetising force was raised to higher values, at which this proportionality no longer held good. As before, the compensating coil was adjusted for each current to balance the effect of "make;" the iron was being demagnetised by reversals immediately before the "make." When a stronger current was applied, the coil had to be pushed

Digitized by Google

nearer the magnetometer; but up to forces of 0·3 C.-G.-S. or so, it was practicable to secure an instantaneous balance by doing so. Observations of the drift were taken at 5 and 10 second intervals during 1 minute.* These are given on p. 273, the equivalent effect of the compensating coil being added in each case to the actual magnetometer readings.

In Fig. 2, curves are drawn to show the relation of the current to (*a*) the immediate magnetisation; (*b*) the magnetism after five seconds; and (*c*) the magnetism after one minute. The gradient of the curve (*a*) at and near the origin is the same as that of the corresponding curve in Fig. 1, when allowance is made for difference of scales. In the present instance one division of current is 0·0013 of $\mathfrak{H}$, and one division of magnetism is 0·008 of $\mathfrak{A}$. The gradient begins to increase very sensibly when $\mathfrak{H}$ exceeds about 0·07.

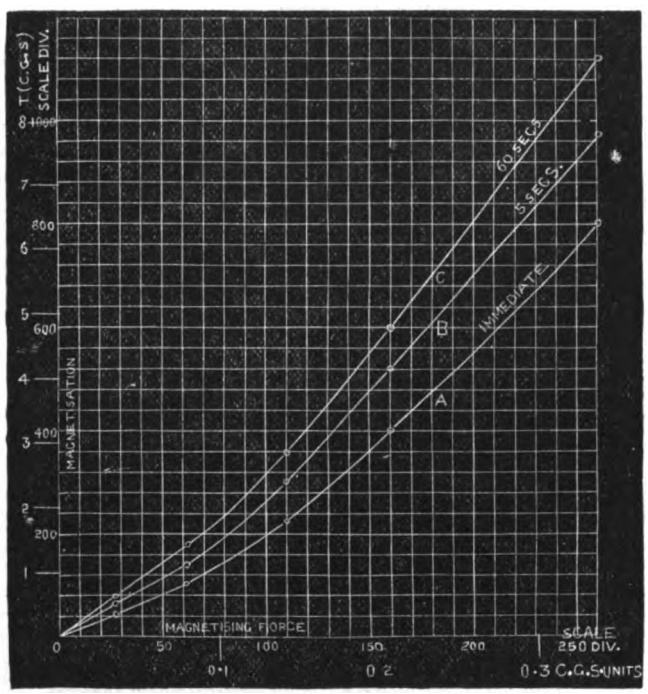

FIG. 2.

Some of the results of Table I are also shown in Fig. 3, which gives time curves of the growth of magnetism for the first two stages (currents 27 and 62). Similar curves for the other stages may readily be constructed from the table. It should be noticed that the time rate of creeping is by no means excessively great in the first instants after contact is made; it is on this fact indeed that the practicability of the method depends.

TABLE I.

Time after "make."	Current.				
	27	62	110	161	161

15	74	165	339	573	1089
20	77	169	344	581	1098
25	79	171	347	586	1104
30	79	173	350	590	1109
40	80	175	354	595	1116
50	80	177	355	598	1120
60	80	177	357	600	1124

Similar differences between the immediate and ultimate increments of magnetism present themselves when the magnetising force is increased step by step. In the following experiment the compensating coil was set so as to balance the immediate effect of a feeble magnetising current. Then such a current was applied, and the creeping up of the magnetism during one minute was observed. At the end of the minute the current was increased by a small step, and it was found that the compensation was still correct or very nearly so; in other words, that the immediate effect of this small increase of magnetising force bore the same or very nearly the same proportion to the increment of force as at the beginning of the process of magnetisation. The creep up of magnetism was again observed during a minute; then another small step up of the current was made, and so on. The compensation remained nearly correct for a number of steps, but as the process was continued up the curve of magnetisation, it became apparent that the immediate effect was *increasing*; in other words, that there was under-compen-

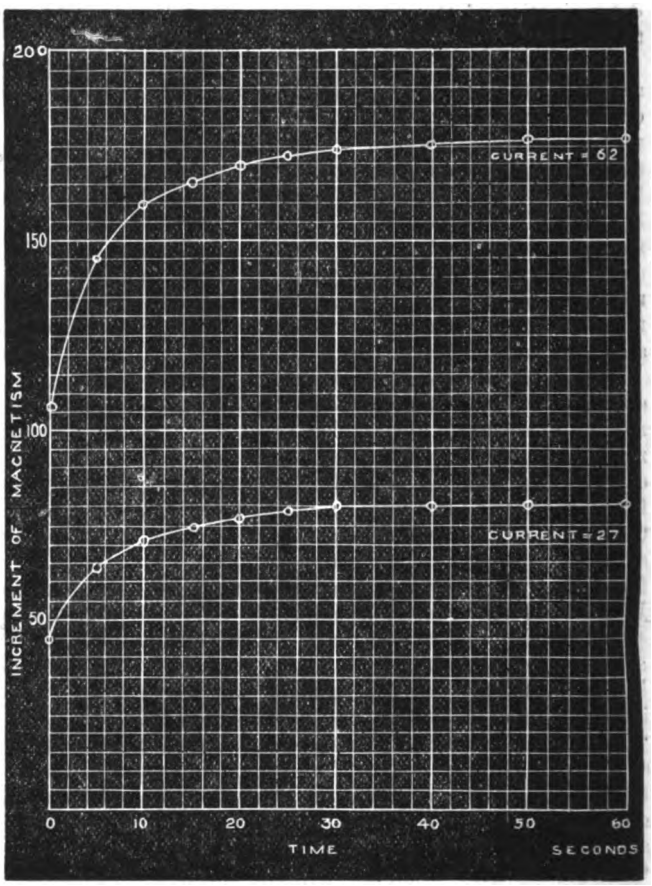

FIG. 3.

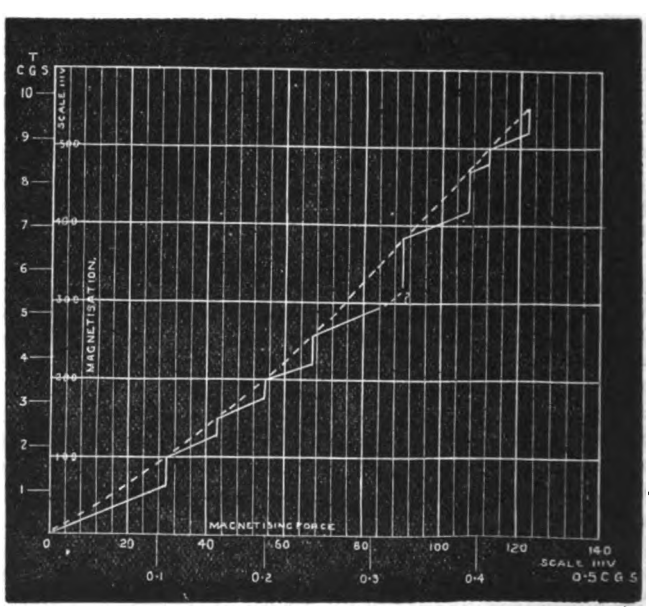

FIG. 4.

* To make the drift large the top of the wire was this time only 4 centimetres from the magnetometer.

Digitized by Google

sation, and that the compensating coil would have to be moved a little forward if an exact balance was to be maintained. The results of this experiment are given below (Table II.), and are exhibited in Fig. 4. The magnetising current was increased from one to another of the successive values shown in the table at intervals of one minute in each case by moderately quick movements of the sliding block in the liquid rheostat. The changes of magnetic force were, therefore, not quite sudden; each of them took, perhaps, a quarter of a second to complete.

TABLE II.

Magnetising current.		Immediate magnetic effect of step.	Additional increase of magnetism in 1 min.	Total magnetism after 1 min.
Step.	Total.			
30	30	63	36	99
13	43	27	23	149
14	55	26	22	197
12	67	25	35	257
23	90	(49+)	(75−)	381
17	107	36	53	470
5	112	10	22	502
10	122	21	33	556

The step of 23 was too large to have its immediate effect balanced by the compensating coil in the position in which the coil was set. The magnetic effect of such a large step is conjecturally shown by the broken line marked (?) in Fig. 4. It will be noticed that the points reached after one minute at each step lie well on a continuous curve, which is shown by a dotted line in the figure.

In Table II. and Fig. 4 one scale division of magnetising current is equivalent to 0·00362 C.-G.-S. units of magnetising force, and one scale division of the magnetometer is equivalent to 0·0177 C.-G.-S. units of $\mathfrak{I}$. The immediate value of $d\mathfrak{I}/d\mathfrak{H}$ is about 10, as before, and this applies approximately throughout the range of magnetism dealt with here, with a slight increase towards the upper end of the range.

Higher up in the curve of magnetisation, however, the immediate effect of a small, quick increment of magnetic force is greater, though then (owing to the greater steepness of the curve $\mathfrak{I}$ and $\mathfrak{H}$) it bears a smaller proportion to the ultimate effect. This is well shown in the following experiment (Table III. and Fig. 5).

TABLE III.

Magnetising current.		Magnetising effect.	
Step.	Total.	Immediate.	Additional in 1 min.
...	461	...	...
15	476	19	61
13	489	17	55
11	500	14	50
15	515	19	69
32	547	(41+)	(142−)

Here the last step was too large for perfect compensation. One scale division of current corresponds to 0·0021 C.-G.-S. units of magnetising force, and one scale division of the magnetometer corresponds to 0·022 of $\mathfrak{I}$. The immediate susceptibility to small increments of force, $d\mathfrak{I}/d\mathfrak{H}$, is now about 13. The magnetic viscosity is now so great that this immediate effect is less than one-fourth of the whole change which the magnetisation has suffered by the time 1 minute has elapsed.

To show clearly the region in the curve of magnetisation at which the experiment of Table III. and Fig. 5 was made, a curve is drawn in Fig. 6, showing, as the result of a separate experiment, the relation in absolute measure of the intensity of magnetism to the magnetising force produced by the solenoid. The region dealt with in Table III. is at the place marked Q ($\mathfrak{I}$ = about 40 C.-G.-S.), and the dotted line drawn there shows the immediate value of $d\mathfrak{I}/d\mathfrak{H}$ after a 1-minute pause. The dotted line P shows the corresponding initial gradient, or immediate value of $d\mathfrak{I}/d\mathfrak{H}$, when there is no previous magnetisation.

Another step-by-step experiment of the same kind, made at a place higher up, where the magnetising force of the solenoid was about 4 C.-G.-S. and $\mathfrak{I}$ about 320, gave again about 13 for the immediate effect ($d\mathfrak{I}/d\mathfrak{H}$); and this was followed by a creeping to the extent of six or seven times the immediate effect.

The immediate magnetic effect of a small step is substantially the same whether the step is made quite suddenly by short-circuiting a resistance coil in the circuit of the magnetising solenoid, or comparatively gradually by means of the liquid slide, so that the process occupies a sensible fraction of a second, or even as much as a whole second.

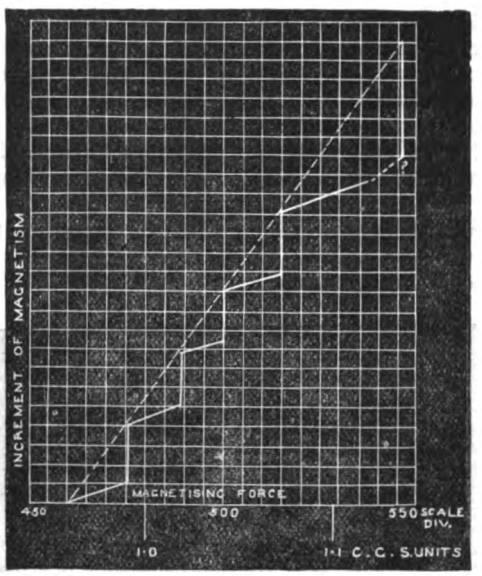

FIG. 5.

However small the step is, it appears to be followed by a creeping up of magnetism. I have been able to discover nothing which would correspond with the limit of perfect

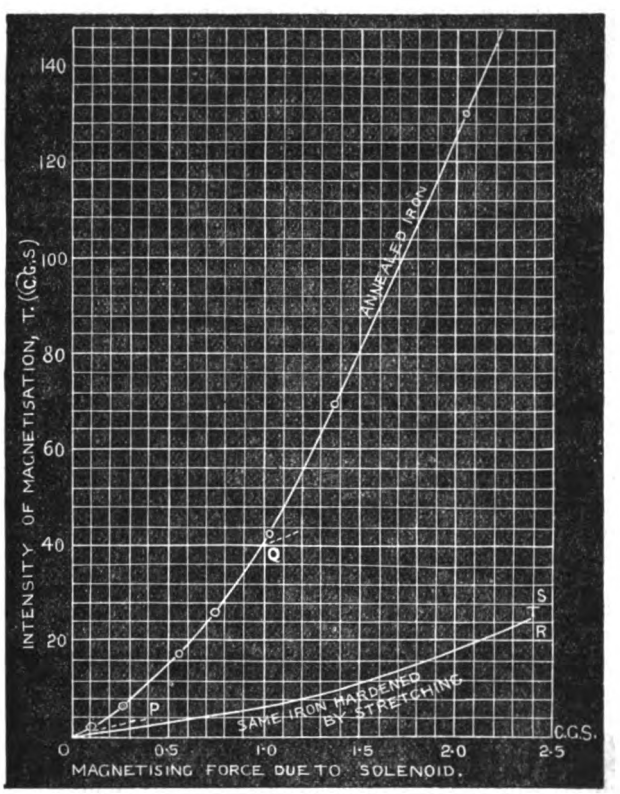

FIG. 6.

elasticity in straining a solid (if there be any true limit of elasticity), either in the initial part of the process of magnetisation, or after the prolonged application of a constant magnetising force.

Digitized by Google

But the prolonged application of a constant magnetising force produces an effect which is a most interesting analogue of one effect of prolonged loading in a stretched wire. It is well known that when a load (sufficiently great to produce permanent set) is applied to a stretched iron wire, there ensues, with the lapse of time, not only a certain amount of supplementary viscous extension (the analogue of the magnetic creep), but also a quasi-hardening of the metal which becomes manifest when an addition is made to the load.* One effect of this is that the wire responds with great sluggishness to the additional load, and this sluggishness is greater the longer has been the preceding interval during which the load has been maintained constant. To test whether, in like manner, the prolonged application of a constant magnetising force would produce what may be called magnetic hardening, I have made comparative observations of the time-rate of change of magnetism when a definite small increment of force is applied, the preceding force having been kept constant (*a*) for a short time and (*b*) for a long time. The result is to show that the process of magnetic creeping after a small step is much slower when the preceding force has been in action for a long time than when it has been in action for only a short time.

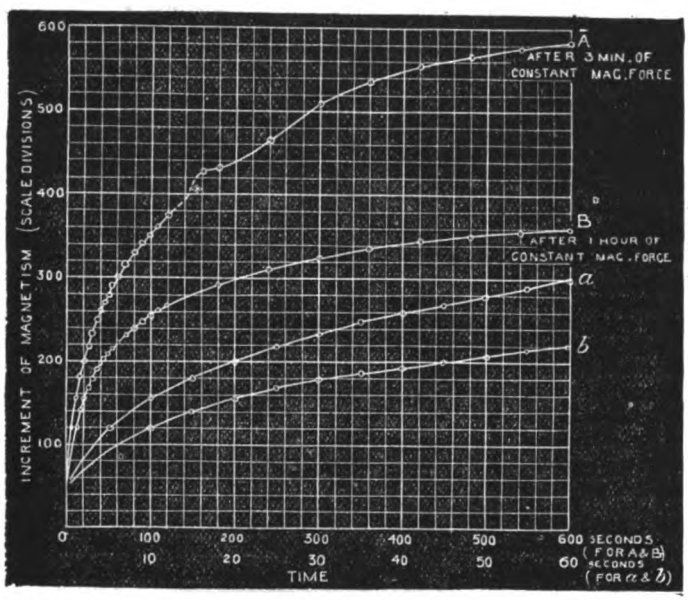

FIG. 7.

The following experiment illustrates this well. After raising the magnetising force to between 2 and 3 C.-G.-S. units, the compensating coil was adjusted to balance the immediate effect of a small increase of force, this increase being brought about by short-circuiting 1 ohm (out of many ohms) in the magnetising circuit. When the compensation had been adjusted, the iron was demagnetised by reversals, and the magnetising force was again gradually applied. When it reached the value of 2·54 C.-G.-S., a pause was made for 3 minutes, during which time this magnetising force of 2·54 remained constant. The resistance in the circuit of the magnetising current was then suddenly reduced by 1 ohm, which had the effect of raising the force to 2·60. The compensating coil prevented this step-up of magnetising force from having any instantaneous effect on the magnetometer; but creeping, of course, began at once, and the time-rate of creeping was observed during 10 minutes. Then the magnetising current was kept constant for 50 minutes more, making 1 hour in all, and a second step-up of magnetising force was effected by removing another ohm of resistance: the second step was very nearly equal to the first, and raised the force to 2·66 C.-G.-S. The time-rate of creeping which followed it was also observed during 10 minutes. The results are shown in Fig. 7, where the curve A shows the growth of magnetism during 10 minutes when the step had been preceded by a 3-minute interval of constant force, and the curve B shows the growth of magnetism when a sensibly equal step was made, which had been preceded by a 1-hour interval of constant force. The times are in each case reckoned from the instant at which the step was made, and the increment of magnetism is in each case reckoned from the value reached just before the step was made. The immediate effect of each step (balanced by the coil) was equivalent to 51 scale divisions of the magnetometer. The creeping-up in 10 minutes was equal to no less than 531 scale divisions in the case of curve A, as against 320 in curve B. At the place marked with an asterisk in curve A, it happened that the laboratory door was slammed, which shook the wire very perceptibly and caused a comparatively sudden increase of magnetism (indicated by the dotted part of the curve), after which the time-rate of creeping became specially slow for one or two minutes; finally, however, the rate appeared to recover from this disturbance. The curves *a* and *b* of Fig. 7 are the first parts of A and B drawn to a ten-fold coarser scale of times.

In confirmation of the above, another experiment was made, in which the magnetic force was increased by three successive small and very nearly equal steps. The first step was made after 5 minutes of constant force, the second after 1 hour of constant force, and the third again after 5 minutes of constant force. Time-curves of the growth of magnetism were drawn in all three cases. The first and third curves were not far from coincident; but the second curve lay very much below them, as B lies below A.

In the experiments to which Figs. 4, 5, and 7 relate, the increment of magnetic force whose effects were measured was preceded by increasing magnetic forces; in other words, it was a step-up from a point on the *up* curve of magnetisation. I have also examined the effect of a small *step-down* from a point on the up curve—that is to say, a small decrement of previously increasing force—and find, as might perhaps be anticipated from what we knew about static hysteresis, that the immediate effect ($d\mathfrak{I}/d\mathfrak{H}$) of a step-down is decidedly less than the immediate effect of a step-up. When the compensating coil had been adjusted to balance the first effect of a step up, it was found to give over-compensation for a step-down.

Another process has been examined, namely, the alternation of a step-up with step-down, many times repeated. After the magnetising current had been raised to a certain value, it was periodically altered through a definite narrow range by alternately putting in and pulling out the short-circuit plug of a small resistance coil in the main circuit, or by making and breaking a feeble circuit in a second solenoid wound over the first. It was only when this process had been repeated many times that the magnetic effects of the small changes of $\mathfrak{H}$ became approximately cyclic; the early cycles were associated with a progressive rise in the intensity of magnetism. But when a nearly cyclic state was reached, the compensating coil could be adjusted to balance the immediate effects of $+\delta\mathfrak{H}$ or $-\delta\mathfrak{H}$, and the same adjustment, of course, served to balance either.

Tested in this way the gradient $d\mathfrak{I}/d\mathfrak{H}$ (for the immediate effect of $\delta\mathfrak{H}$ after many small + and − steps) has, of course, a lower value than the gradient which is found when $\mathfrak{H}$ is first raised to $\mathfrak{H}+\delta\mathfrak{H}$). The latter, as we have seen, is greater when the magnetisation is moderately strong than when there is little or none. The former is nearly constant throughout a wide range of $\mathfrak{I}$; its value is approximately the same as at the initial part of the magnetisation curve—namely, 10—until the region of saturation is approached, when it becomes distinctly less.*

The periodic changes of magnetism which are brought about by successive small increments and decrements of $\mathfrak{H}$ exhibit a lagging and creeping up and down precisely similar to that which has been illustrated in Fig. 1. That figure may serve to show in a general way the relation of the change of $\mathfrak{I}$ to the change of $\mathfrak{H}$, when at any place in the curve a very small increment $\delta\mathfrak{H}$ has been applied and removed often enough to establish a cyclic *régime*. I have not made any full examination of the variation which under these conditions the gradient $d\mathfrak{I}/d\mathfrak{H}$ suffers when the magnetism on which the small cycle if superposed is gradually pushed up towards saturation, nor of the proportion which the subsequent creeping up or down

bears to that part of the change of $\mathfrak{J}$ which occurs immediately on the application or removal of $\delta\mathfrak{H}$. The creeping which follows each repeated application and removal of $\delta\mathfrak{H}$ is certainly much reduced when the iron approaches saturation; but the immediate effect is also reduced, and so far as may be judged by rather rough determinations, it appears that the proportion of creeping to immediate effect is much the same with high as with low magnetisation.

One may refer, in this connection, to the energy which is dissipated through hysteresis, in performing a small cycle by alternately applying and removing a very small force $\delta\mathfrak{H}$. The action is the same in kind whether there is or is not additional magnetisation. The energy dissipated in each cycle is $-\int \mathfrak{J}d\mathfrak{H}$, and vanishes when the increment and decrement of go on *pari passu* with the increment and decrement of $\mathfrak{H}$.

Consider now Fig. 1. When the repeated cyclic changes of $\mathfrak{H}$ are indefinitely rapid and go on without pause, so that creeping has not time to occur, a single straight (or sensibly straight) line such as O A represents the relation of the change of magnetism to the (very small) change of magnetising force, during both increment and decrement. The rapidity of the action prevents any loop from being formed, and there is consequently no sensible dissipation of energy through hysteresis. This state of things is perhaps nearly realised in the case of a vibrating telephone diaphragm, or, in regard to circumferential magnetisation, by an iron conducting wire in a telephone circuit. Again, let the cycle be performed indefinitely slowly. In that case the magnetism, at every stage of the cycle, creeps up or down to a steady value. A sensibly straight line, such as O B, represents the relation of $\mathfrak{J}$ to $\mathfrak{H}$ during both increment and decrement; and there is again no dissipation of energy. But with any frequency of alternation lying between these extremes of infinitely fast and infinitely slow, a loop will be formed, since the creeping will take effect most considerably at and near the ends of the range (the time rate of change of $\mathfrak{H}$ being least there), and there will be dissipation of energy. When the limits and mode of variation of $\mathfrak{H}$ are specified, there must be some particular frequency which will make the energy dissipated per cycle a maximum.

The phenomena described in the Paper have been reproduced in several specimens of annealed iron wire, of course with quantitative differences. As to the amount of magnetic creeping, much depends on the annealing of the specimen. Another piece of iron wire cut from the same bundle as the piece with which these experiments were made, and annealed at another time, showed almost exactly the same susceptibility to magnetism as the first piece, so far as immediate effect went; but in it the subsequent creeping up was decidedly less (in the proportion of about 4 to 5).

When the iron is hardened by mechanical strain the phenomena of creeping vanish almost completely. A specimen from the same bundle was annealed, and showed much creeping. It was then put in the testing machine and pulled until it took a set of 1 or 2 millimetres in a length of 40 centimetres or so. It was then examined magnetically as before, and scarcely a trace of creeping could be observed when a feeble magnetising force was applied. When the compensating coil was properly adjusted the making or breaking of the magnetising current caused no more than a slight momentary quiver of the magnetometer needle, followed by no measurable drifting, although the whole magnetic effect (compensated by the coil) was equivalent to a hundred or more scale divisions. When a magnetising force of as much as 0·6 C.-G.-S. units was suddenly applied, the amount of creeping, if there was any, was certainly less than 1 per cent. of the immediate effect. With values of $\mathfrak{H}$ higher than this it became possible to detect creep with certainty. The following notes relate to this wire :—

Magnetising force suddenly applied. (C.-G.-S.)	Immediate value of $\mathfrak{J}$ (C.-G.-S.)
0·75	4·49
1·28	8·42, crept in 1 min. to 8·58
2·40	25·5 „ 26·4

These forces were in each case applied to this wire in a neutral state. Another trial of the same, with feebler forces, gave 5·3 as the value of $d\mathfrak{J}/d\mathfrak{H}$ for the immediate effect of a very small force, applied when the iron was demagnetised. The same quantity in the annealed specimen was, as has been said, about 10. In Fig. 6 the relation of $\mathfrak{J}$ (immediate) to $\mathfrak{H}$ as stated above, is represented by the curve O R; the creeping up at the last point is R S.

In speaking of soft iron it has been shown that the effects of creeping are most marked when a small addition $\delta\mathfrak{H}$ is made to a previously increasing force $\mathfrak{H}$. In instances quoted above, the creeping up in 1 minute has under those conditions been many times greater than the immediate effect of $\delta\mathfrak{H}$.

By way of putting the specimen of hardened iron to the same test, I have applied a magnetic force of 1·46 and raised it by a small step to 1·49. The immediate effect of this step (which was balanced by the compensating coil) was equivalent to twenty-two scale divisions of the magnetometer, and this was followed during 1 minute by a creeping equal to six scale divisions. In itself this creeping is considerable, but compared with the corresponding creeping in soft iron it is extremely small.

Pieces of steel (containing a good deal of carbon) have also been examined, with the result that whether the steel be annealed or in its commercial temper the phenomenon of creeping is even less visible than in hardened iron. With annealed steel, a force which produced an immediate (compensated) magnetic effect equal to 124 scale divisions caused barely a single scale division of creeping. With a stronger current, giving an immediate magnetism of 340, the subsequent creeping was 3. In steel and in hard iron the creeping seemed to be completed in a few seconds after the institution of the magnetising current. The steel specimen, like the iron, had a diameter of rather more than 4 millimetres. Its susceptibility (annealed) was considerably less than that of the iron in the hard state.

It is scarcely necessary to observe that the protracted and extensive creeping or magnetic "nachwirkung" in soft iron which these experiments illustrate cannot be ascribed to the subsidence of the circumferential currents which are generated by the imposition of longitudinal magnetic force. The creeping is equally conspicuous whether the magnetic force is suddenly or gradually imposed. Lord Rayleigh has shown that circumferential currents started and left to themselves will subside to e^{-1} of their initial magnitude in the time

$$\tau = \frac{4\pi\mu a^2}{(2{\cdot}404)^2\rho},$$

where a is the radius of the cylinder, μ its permeability, and ρ its specific resistance.* In the present instance, taking the case of the annealed iron rod, $a = 0{\cdot}202$, $\mu = 125$, $\rho = 9827$ (Everett), and τ is less than $\frac{1}{1000}$th of a second. The subsidence would be practically complete in a small fraction of a second; but the creeping persists during many seconds and even minutes with no excessive change of rate. Again, comparing soft iron with hard iron, in which μ is less and ρ is greater, the values of τ will differ, but not by any means so much as to correspond with the very wide difference in magnetic lag.

In view of this it is puzzling to find that the diameter of the rod experimented upon has a most important influence on the magnetic lag.

In testing various samples of soft iron wire, most of which were of less diameter than the piece used in the above experiments, I noticed that the phenomena of creeping were less marked in the smaller rods. I then tried a bundle of nine very soft annealed iron wires, which were bound together with fine copper wire, and formed a core of about the same length and aggregate diameter as that of the solid rod formerly used. With this bundle there was some creeping, but very little in comparison with what was observed in the solid rod, as the figures in the table on the following page will show.

Finally, another bundle was built up, consisting of a much larger number of fine annealed iron wires. With this the creeping was almost insensible.

It may be that the comparative absence of magnetic creeping, or "nachwirkung," in these last experiments is to be ascribed

* "Brit. Assoc. Report," 1882, p. 446.

to the quickness with which the process of creeping completes itself in a finely-divided mass of iron; in other words, that the process is practically complete in a time much shorter than the period of the magnetometer needle. The marked difference in effect between a solid core (a single thick wire) of soft iron and a laminated core (a bundle of fine wires) of the same material suggests that in the former much more than in the latter the process of creeping is retarded by the eddy currents which are set up by those molecular movements in which the process itself consists.

[July 11th.—In seeking an explanation of the difference in behaviour it may be worth while to bear in mind that there is probably a considerable difference in molecular structure between a solid core and a laminated core of iron. If we accept the view that the magnetically neutral state is due to the molecular magnets forming closed rings, these rings will for the most part be closed within the limits of the separate constituent pieces of the laminated core, whereas in the solid core they may be much larger, their dimensions being limited only by those of the core itself.]

I have received very valuable help in these experiments from two students, Mr. David Low and Mr. William Frew, who have prosecuted a troublesome research with much patience and zeal.

PRECAUTIONS TO BE ADOPTED WHERE A SUPPLY OF ELECTRICITY IS FURNISHED BY MEANS OF TRANSFORMERS.*

BY KILLINGWORTH HEDGES, M.I.C.E.

In a Paper entitled the "Fire Risks of Electric Lighting," which was read at the meeting of the British Association held in Southport in 1883, I brought forward for the first time the necessity of electric light regulations and the use of safety appliances. The fire insurance companies have almost universally recognised that the electric light can only be considered a safe illuminant when the strictest attention is paid to the details of an installation; and the regulations which have been published by the principal companies and by the Institution of Electrical Engineers have so far proved successful, as no fire of magnitude can be traced to the electric light. The introduction of transformers has led to the increase of the electromotive force in the primary mains, and there appears to be a tendency to decrease the pressure in the secondary, consequently there is an enormous difference of potential between the two systems and a constant strain on the insulation of the transformers. A transformer may be compared to the reducing valve which converts high-pressure steam into the safe pressure for working heating coils. There is, however, this difference—a transformer never sticks like a valve, but it sometimes leaks, and the consequences are similar to those arising from a leaky reducing valve. Supposing a small leak to take place between the primary and secondary coils, it is quite possible that a small current of dangerously high potential might be introduced into the secondary circuit, which would make very little difference to the light from the lamps, but might cause fatal results on any one inadvertently touching some unprotected portion of the wires or fittings with one hand and a gas pipe with the other. To produce this effect it is necessary that some earth should occur on the primary main or mains. With the overhead wires which have almost universally been employed, with alternating currents of high E.M.F., any leakage to earth may be avoided, but with an underground system, and with the increased pressure which is about to be introduced, there is sure to be some earth connection; in fact, with the Ferranti system, one of the conductors is to be earthed throughout. Allowing that a possible danger exists, the question is to find a safe preventive, and with this object it is proposed to briefly recapitulate what has been done. Mr. Kent inserts a metallic shield between the primary and secondary coils of the transformer; this sheet of metal is connected to earth. Now, if the insulation of the primary coil should fail, the leak before reaching the secondary coil must pass through the sheet of metal and thus to earth, causing the primary cut-out to melt and thus cutting out the faulty transformer. The next plan is still simpler, and is to earth the secondary circuit, so that the effect of a contact in the transformer would be to establish connection through the earth and to blow out the primary fuse as in the previous method. It has been stated by several high authorities that this arrangement is all that is wanted to secure perfect safety against shock, but the question of fire risks has also to be considered, and these would be greatly increased, also the insulation of the wires in houses would have to be of the most expensive character. Allowing that every care had been taken with the insulation, the proximity of gas and water pipes in a house to the wires, which are often laid under floors, might open a path for the deviation of a leakage current, say of 2,000 volts or over, and an arc once formed would result in a dangerous fire. The fire insurance offices have not sanctioned this plan, which does not even appear to be used in those go-a-head institutions, the electric light companies of the United States, who apparently employ no safeguards, and trust to Providence with regard to the "burn out" of a transformer, having a ready supply of duplicate parts to at once replace in the faulty instrument. We now come to the intermittent earth device, that is the automatic apparatus which only comes into play when the potential in the secondary has dangerously increased. Dr. Fleming has described an instrument which consists of a fine-wire safety catch holding down suitable contact pieces in mercury cups against the pressure of a spring. The safety catch would be arranged to stand the normal difference of potential between the two secondary mains, but as soon as that rose beyond a certain amount the circuit would be automatically broken. This plan has the disadvantage of a certain amount of loss of current, which would be, however, checked by a resistance; but it avoids the necessity of using an earth.

Fig. 1.

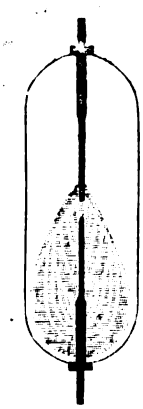

Fig. 3.

Bernstein advocates his contact plug, which contains a substance, the resistance of which can be made enormous with the normal current, but the heating effect of an increasing current causes the mixture in the plug to be decomposed, and a metallic circuit established. I am unaware whether this has been tried in a circuit from a transformer or not, but am afraid it would not answer in practice. Major Cardew, whose improved apparatus I have the pleasure of showing you to-day, has, so far, produced the most successful device. It has been called the static mouse-trap (*see* Fig. 1), in that it goes off directly an unauthorised volt enters it. The arrangement which you see on the table takes the form of a box; in it there are two brass discs, separated one from the other by an insulating washer of ebonite. Between the two discs is placed a small strip of

* Paper read before the British Association in Section G, Newcastle-on-Tyne, September, 1889.

Digitized by Google

aluminium foil which lies in ordinary on the lower disc, which is connected to earth. The other disc is in connection with the secondary coil of the transformer, and should any leakage take place from the primary so as to raise the potential in the secondary say by 50 per cent., that part of the aluminium foil which is under a projection on the upper disc will be attracted to it, making an electrical connection and starting an arc which short circuits the secondary and causes the primary fuses of the transformer to be melted. Working quite distinctly from Major Cardew, I have also designed a safety appliance, which may be called a "vacuum cut-out." It is on the lines of those lightning protectors which are often used with telegraph cables, but the electrodes are fixed at each end, and cause the current on its way to earth, after leaping across the points, to energise an electro-magnet which releases a short-circuiting device connected with the primary poles of the transformer (Fig. 2). There is one great advantage in my vacuum cut-out, in that it is not affected by dust or moisture, which might impede the static arrangement. In practice, I propose using old incandescent lamps, with their broken filaments sprung, as they often are, one-sixteenth apart. The perfect vacuum must, however, be destroyed, or only high potential will pass, and the current will preferably short circuit across the terminals instead of leaping across the broken filament. A lamp of this description would cost very little, and could be fixed in the same manner as the Cardew cut-out, without any relay. Numerous experiments were made to ascertain the distance which an alternating current would leap across points in tubes exhausted to a certain amount. The results differed considerably from the figures given by De la Rue in his experiments with continuous currents. In one experiment with glass cylinders having conductors hermetically sealed in opposite ends, and with a pressure of 5m/m, less than that equal to a perfect vacuum, an alternating current of 1,000 volts invariably passed between the ends of the copper electrodes, which were ·3 inches apart.

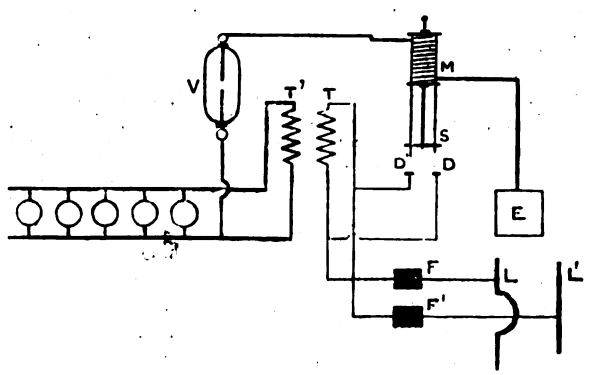

FIG. 2.—V, vacuum cut-out; M, electro-magnet; S, short circuiting device; D D¹, stops for ditto; E, earth; F F¹, fuses; L L¹, main leads; T T¹, transformer coils.

The arc (Fig. 3), however, did not remain steadily at the ends, but would first run down one electrode to the point where it was connected to the platinum wire, which came through the glass, with the result of fusing it away. The arc would at the same time extend almost to the glass, although the opposite electrode was left intact. The reason of this phenomenon with an alternating current may be perhaps explained in the discussion. In conclusion, I think that all those who intend using high-tension alternating currents for the supply of electric light and power, should be obliged to fix a safety device on the secondary circuit, near the transformer, with the object of not only protecting their own property, but also to do away with the possibility of an unauthorised current being inadvertently led into a building so as to endanger the lives of the public.

DISCUSSION.

Mr. PREECE had one word to say as regards the dangers. When he spoke the other day he referred solely to dangers to persons, but to-day they had heard more about dangers from fire. It was a great mistake to imagine that an electric lighting system was entirely free from risks of fire. It was often said, "Oh, have the electric light in your house and you will be absolutely safe; there is no fear of your house being burnt down." But that was a very great mistake. There was not the slightest doubt about it that there was nearly as much danger—not quite—from introducing the electric lighting as there was from introducing gas. Gas, of course, was much more dangerous, but there was danger in introducing the electric light, and the chief danger arose from the use of imperfect material, and especially from the employment of inexperienced men, and also from the want of just those very contrivances which Mr. Killingworth Hedges had brought before the Section. If good material was used, if experienced men were employed to lay down wires, and if all the apparatus of safety such as they had heard of from Mr. Hedges be admitted, then electric lighting is absolutely safe, but not unless they did something of that sort of thing. As regarded dangers to persons, that was quite a different thing. He had alluded the other day to a strange remark made by Mr. Stephenson. One of the reasons he had adduced against the distribution of power by means of electricity was that if a man touched the wire he would be killed. Well, in unscientific language, that is absolute rot. The difficulty with electric currents is not to prevent them from killing, but to kill a man. The State of New York recently passed an Act making execution in the future execution by electricity. They had not rescinded that Act yet, but they would be obliged to do so, because they could not determine the electric current which would kill a man with certainty. He remembered on one occasion making some experiments with an enormous induction coil by Apps. They did all they could with a spark 20in. long to kill a rabbit, and they could not. They volunteered to try him, but he was not quite ready to offer his body when other animals could be found. There were many who had taken immense shocks. Colonel Armstrong at Chatham took shocks that were supposed to kill individuals, but he was very well afterwards. He could really say this from some experience of electricity, that with ordinary precautions there absolutely is no danger to person, there is no danger to life, and much that is said about it is nonsense. Newspaper correspondents, as a rule, were very fond of getting up sensational paragraphs, and the newspapers very often put them in. There was a case in Brighton only three weeks ago, where a brewer's man was stated to be killed by the electric light currents. Certainly the man was dead; he was found resting against a wire; there was a mark on the back of his neck which showed some indications that he might have been killed by electricity. But the fact was that the electric light current was stopped some two hours before the man was supposed to be killed, so that when the man was killed there was no electric current from the electric light station. There might have been lightning—there was a thunder-storm at that time—but it is doubtful whether the man in Brighton was killed by currents generated by the central electric lighting station established there.

Mr. KILLINGWORTH HEDGES, in reply to Mr. Powell, said he did not mean to say in his Paper that the fire risks were greatly increased; he had meant to say that they were practically settled, and that the dangers could be minimised by the precautions which the insurance offices insist upon before they pass the insulation. He thought something the same would eventually be done with the question of danger through shocks. He was rather in the position of the rabbit described by Mr. Preece. He had had a very severe shock, and had been told that he had made a great mistake. He thought Mr. Preece could hardly have meant that the insulation of an underground system was perfect. He happened to have with him the discussion on a Paper read in 1888 on the distribution of electricity by means of secondary generators and transformers. In the discussion Major Cardew said that the subject had given anxious consideration to the Government, in that the conductors with transformer systems may acquire at any time a potential difference of 2,400 volts from the earth, and that in all underground mains there is a resultant leak. Therefore, as the other conductor has also a resultant leak, and this is not likely to offer a resistance of many thousand ohms, there is a danger that, if conditions are favourable, the whole system of transformers may break through, and hence prevention is better than cure—one should be prepared for this. I do not mean to say that it is going to occur at once, but I think one ought to admit that there is this chance, and try some special device. As regarded the mains of the London Electric Supply Company, the shareholders were to be congratulated that the system, beautiful and ingenious as it is, is not going to be used now, because it seemed too much of an experiment to lay down that enormous amount of main on quite a new system, and a system which he thought had never been tried experimentally.

Junior Engineering Society.—Prof. Perry has accepted the presidency of the Junior Engineering Society for the ensuing (the ninth) session, which he will inaugurate by the delivery of an address on "Mechanical Engineering in Electrical Industries." This lecture will be delivered on Friday, October 11, at the Westminster Palace Hotel.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 14, 1889.

The Postal Telegraph Company, which, as you are aware, has Mr. John Mackay behind it, has been very busily engaged for a long time in developing its service on the Pacific Slope. It now proposes building lines through Oregon and Washington Territory, connecting interior points with the large cities on the Pacific. This work will be begun early next spring. At the present time the company is actively occupied also in developing its service through the South, and it is stated that it will spend over four million dollars this year in Southern States. One of the lines to be built will run along the Atchison, Topeka and Santa Fé road to the Pacific Coast. The company will also probably buy up one or two of the smaller companies which exist in the South, and will thus only follow the example of the Western Union Company, which has but just recently completed such a purchase. Mr. Mackay has been in this city for some time past, occupied with the affairs of his company, and with the Commercial Cable Company, whose capital stock has been increased from $6,000,000 to $10,000,000, and is now going on the Stock Exchange, where its friends expect to see it rank with other established 6 per-centers.

The subject of electric railways is fast becoming a leading one in many of our Western cities. The example that Boston has set in going in boldly for electricity as the motive power for its street railways has very effectually arrested the attention and stimulated the enterprise of Western street-railway magnates, and the consequence is that we see a large quantity of new work and hear of more very big projects. Last week I mentioned what is being done in Cincinnati. The same activity prevails at Cleveland, Ohio, and other places. St. Paul, Minnesota, determined not to be left behind, has gone in at a great pace, and last week granted ordinances to no fewer than four companies. A peculiarity of one of these franchises is that it is granted to Archbishop Ireland, of the Roman Catholic Church, and it is supposed that this well-known dignitary proposes to invest church funds in the enterprise. This is wholesale work, but, as in the case of Boston, the city newspapers approve the action, and there is no doubt that St. Paul will soon have several fine roads running. At St. Louis electric roads are beginning to attract considerable attention, and while this city has been considered one of the strongest centres of cable-road influence, it seems more than likely that ere long it will be just as much an electric city. One of the reasons why the cable roads in operation there were so popular and successful was that they competed with parallel horse roads. As soon, however, as these parallel lines were cabled, the more enterprising companies saw that the public wanted further improvements, and they are thus about to adopt the electric motor, not simply because it will afford better transit facilities, but because it will serve to cut down operating expenses.

It is becoming the practice here to introduce the electric light in the various State institutions, prisons, &c. The best results have attended this improvement, and it will not be long before such places without the electric light will be the exception rather than the rule. One of the latest instances of the kind is that at Michigan City, Ind., where the incandescent light has been adopted for the Northern Indiana Penitentiary. There are 700 cells in this place. Hitherto the prisoners have been allowed candles, each of which, of course, had its attendant danger, and had to be extinguished individually. Now, however, the lights will all be extinguished at once, and "on time," and there will be less fear and probability of fire, while the cells will be more healthfully illuminated.

As might have been expected, the Harold P. Brown revelations have caused considerable talk, and are still the prevailing sensation. Mr. H. P. Brown has offered $1,000 reward for the recovery of his letters that "gave the thing away," and for the detection of the person who stole them. It is remarked by some, however, that Mr. Brown lost something else besides his letters, and offers no reward for that, either considering it irrecoverable or of no value. It is now considered that as the result of these disclosures, amounting, it is claimed, to a conspiracy against the Westinghouse Company, the Kemmler investigation will be reopened, in order that the documents in the case may be made a part of the official record, possibly with interesting supplements and addenda. It is not now very generally believed that the sentence of capital punishment by electricity will be enforced, and the sentiment on the part of the public seems to be that death by electricity would not be the altogether painless and stainless euthanasia that has been depicted. It is somewhat significant that Dr. Peterson, who last year was associated with Mr. Brown in his experiments, has come out in a Paper before the American Science Association, offering some very striking reasons why electrical death is objectionable. He says that the most cogent argument that he can urge against electricity as a death penalty is the complexity of the apparatus required, in comparison with the simple instruments used in hanging and beheading, and shows how numerous the conditions necessary for success are, even outside the apparatus.

The National Telephone Association meets in convention this week at Minneapolis. The attendance will be by no means as large as that at the National Electric Light Association at Niagara Falls, but in its way it will be representative of the great industry that telephony has grown into in this country. As you are probably aware, this Association represents the licensed telephone companies doing business in various parts of the country, and it would be interesting to know just what view the parent company in Boston takes of their proceedings. From all outward appearance, however, the relations have been maintained on a social and friendly basis, and for some time to come they will probably remain that way. It is evidently to the interest of all these companies, which, with the parent company, are in masterful possession of the field, to work together, strengthening and consolidating their influence and position in every way, and where the advantages of co-operative combination are so self-evident, one need not be surprised at the steady maintaining of the *entente cordiale*. Just at the present time the suit of the United States Government against the American Bell Telephone Company is assuming a more definite aspect, but I really do not think that this will trouble the Minneapolis delegates very much. In connection with the Government suit, the claims of Daniel Drawbaugh of the invention of the telephone have lately been revived, on the ground that the blacksmith of Eberly Mills has new evidence to offer of a strong character. It is stated that a paper has been filed in the Patent Office by which the People's Telephone Company has assigned all its rights and title to some sixty Drawbaugh patents and applications for patents to three mutual trustees, Messrs. F. W. Jones, J. R. Bartlett, and H. C. Andrews. These three men have been connected with the Drawbaugh interest for some time, and have gathered all the material into their own hands for the purposes of another fight.

It may be mentioned here that the total valuation put upon electrical industries in this country at the present time is about $600,000,000, nearly all of which, save about $100,000,000 from the telegraphs, is the creation of the last ten or fifteen years. The amount invested in the telephone since 1876 approximates another $100,000,000, leaving about $400,000,000 for electric light and power with miscellaneous industries and manufacturing companies, wiring concerns and the like. It seems that this is a conservative estimate, and we may look for the actual figures when the next census is taken, it being proposed to have a special electrical section for the collection of such statistics.

It seems to be the intention of Mr. George Westinghouse to conduct his electric light business not less aggressively in England than he does here, where something like two hundred local companies have sprung up at his call during the last two years. Mr. H. M. Byllesby, vice-president of the Westinghouse Electric Company, has left for England to build a factory in London, and it is stated here that the company propose to give employment to 1,000 men as soon as they are in operation. If this be so, it will doubtless be very interesting for some of your old-established English electric lighting firms and companies, but I dare say they will manage to hold their own so long as they show themselves abreast of the times. Probably, as has

Digitized by Google

happened before, this new competition, instead of hurting anybody, will stimulate business in every direction and prove highly beneficial in the long run.

CORRESPONDENCE.

ON HYSTERESIS IN THE RELATION OF STRAIN TO STRESS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I would venture to draw Prof. Ewing's attention to the fact that the lagging of mechanical strain behind stress, even when the latter is kept well within the so-called limit of elasticity, has been already shown by Prof. G. Wiedemann for torsion and flexure (*Phil. Mag.*, Vol. IX., Jan. and Feb., 1880; *La Lumière Electrique*, Vol. VI., Nos. 2, 3, 4), and by myself for longitudinal traction ("The Influence of Stress and Strain," &c., *Phil. Trans.*, Part I., 1883). The metals examined by me were unannealed piano steel, iron, platinum, German silver, copper, platinum-silver, brass, zinc, silver, aluminium, tin, and lead.—Yours, &c., HERBERT TOMLINSON.

PROF. PERRY'S VOLTMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with considerable interest and amusement your description of Prof. Perry's latest voltmeter. Although priority claims are usually wholly uncalled for, it may interest Prof. Perry to learn that a precisely similar instrument was devised about three years since by my late colleague, Mr. Ram, and myself. Our voltmeter consisted of a thin and narrow strip of steel fixed at each end and twisted at the centre in the way you describe. Finding it required some forty amperes to work it, we concluded it was merely an ammeter in disguise; moreover, the power wasted was enormous, and the index never returned to zero. We thought it hopeless, and with the carelessness of youth allowed the most "vastly simple" voltmeter to escape. However, it has fallen into good hands, and Prof. Perry is still a comparatively young man.—Yours, &c.,

SYDNEY EVERSHED.

Woodfield-road, Harrow-road, London, Sept. 24, 1889.

THE TESTS OF THE BROOKS' UNDERGROUND SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of last week, through apparently a printer's error, the insulation of the telephone cable, laid on the Brooks' system at the works of Messrs. Johnson and Phillips, was stated to be 88 megohms per mile, instead of 614, as was shown to be the case.

The resistance of the galvanometer used = 12,500 ohms. The deflection through 1·24 megohms, the galvanometer being shunted with 10 ohms, = 37 divisions. Length of each wire tested = 140 yards.

Total length of lead tested = 140 × 7 yards; as all the seven wires were bunched together.

The deflection due to the current passing through the insulation of the whole line (= 980 yards) = 52 divisions.

$$\frac{\frac{G+S}{S} \times 37 \times 1{\cdot}24 \times \frac{980}{1760}}{52} = x.$$

Insulation resistance of each wire = 614 megohms per mile.

You will much oblige me by inserting this correction in your next issue.—Yours, &c. H. C. HALL.

Victoria Works, Charlton, September 25, 1889.

[This test was intended to represent the conditions of an electric light cable, and the seven wires were connected together at one end. Having found the insulation resistance of the whole cable as measured to be 88 megohms per mile, our correspondent wishes to multiply by the number of wires joined in parallel. It appears to us that this is not consistent with the intention of reproducing as far as possible the condition of an electric light cable.—ED. *E.*]

THE ELECTRIC LIGHT AT PADDINGTON—SPECIAL MEETING OF THE VESTRY.

A special meeting of the Vestry was held on Tuesday last to consider what action should be taken with respect to the introduction of the electric light into the parish. The Committee reported that they have held seven meetings, and have devoted considerable attention to the subject. With reference to Resolution 3 of the proposal of Mr. Mark H. Judge and Mr. Mills, the receipt of the Model Order has rendered further consideration unnecessary as regards a uniform basis on which proposals from companies should be made. They have examined the Model Order clause by clause, and recommended the insertion therein of certain protective clauses, and they believe that all requirements for the benefit of the public interests have been duly cared for; and that should the Vestry decide upon employing a private company to supply electric light, they can safely do so on basis of the terms laid down in such Model Order. Touching systems of supply of electric energy, it appears to be quite needless to offer an opinion. Major Marindin in his report expresses a general approval of five distinct systems of supply; and while experts are still at variance as to what may finally prove to be the best, the Vestry may well adopt any system of which Major Marindin has expressed his approval, as to wait until a perfect system has been discovered would delay for years the introduction of the electric light into Paddington. The Committee have applied to the following companies:—The Electricity Supply Corporation (Limited), Metropolitan Electric Supply Company (Limited), House-to-House Electric Light Supply Company (Limited), S. Morse (on behalf of a company to be hereafter named), Westminster Electric Supply Corporation (Limited), London Electric Supply Corporation (Limited), Kensington and Knightsbridge Electric Supply Company (Limited), for definite information as to the price at which they are prepared to supply energy, both for public and private lighting, on the terms laid down in the Model Order. As regards the best mode of public lighting by electricity, there seems little doubt that arc lamps are the most efficient and least expensive. Mr. Spagnoletti, Chief Electrician of the Great Western Railway, entertains no doubt on this point. The installation under his charge in Paddington supplies energy to 100 arc lamps of 3,000 nominal candle-power, and 4,000 incandescent lights. Mr. Spagnoletti calculates that the annual cost of the admirable system arranged by him is not greater than would be that of gas at 2s. 9d. per 1,000 feet. The actual cost of public lighting by arc lights is difficult to arrive at, there being an extraordinary difference in the opinions of experts as to the number required for effective street lighting. Professor Forbes calculates that the lights should be 80 yards apart, and that 21 arc lamps would be required for a mile of streets. Mr. Mackie, on the other hand, considers that 10 arc lamps per mile would be adequate. Mr. Slater stated that the Galway Docks are most efficiently lighted by electricity, the arc lights there being placed, say, 150 yards apart. At Eastbourne 16 arc lights are set up on about a mile of beach, the posts being only 25ft. high, which is considered by the secretary of the Electric Lighting Company there to be too low. The arrangements at Hastings are identical in all respects with those of Eastbourne. At Taunton the arc lights run for an average of eight hours, at a cost of £22. 10s. per light. Taking everything into consideration, it would appear advisable for the Vestry to entrust the work of electric lighting to a well-established company, and in view of the possibility of the Local Authority desiring to purchase at any future time the undertaking of any company in the parish, they consider that it should be a *sine quâ non* that the central station should be constructed, and the distributing mains laid, so as to form a complete installation for Paddington independent of all connection with other parishes. The continuous-current system, in conjunction with storage batteries, as supplied by the Chelsea Company, is considered preferable for private lighting.

There were two motions on the agenda, one by Mr. Judge to the effect that, inasmuch as the Committee has not seen its way to recommend the Vestry itself to undertake to supply electricity for lighting and other purposes in the borough, it is desirable that steps be now taken to secure it being done at an early date by a private enterprise under a Provisional Order approved by the Vestry as the Local Authority; and another by Mr. Minchin:—"That in the interest of the ratepayers, the Vestry do keep the supply of electric lighting for Paddington in its own hands, and in order that such work may be carried out, a capital of not exceeding £50,000 be raised on the security of the lighting rate."

Mr. MINCHIN said that this was one of the most important questions ever brought before the Vestry. One year's delay had already taken place, and it was still in the power of the Vestry, by applying to the Board of Trade, to obtain leave to carry out the electric

Digitized by Google

lighting themselves. He had the two reports. He accepted Prof. Forbes' report, more especially the reasons and suggestions he has given to the Vestry, to do the electric lighting themselves. Mr. Mackie's report was much less ostentatious, but much more practical, and if accepted it could be worked upon. Mr. Mackie was of opinion that £50,000 would be sufficient for these purposes, and if the Vestry agree to his proposal, Mr. Mackie would submit proper estimates in three weeks, which would be all that the Board of Works would require, and the Vestry would get their Provisional Order. St. Pancras had already got such an Order. He hoped Mr. Judge would not strive for a mere waste of time by moving to refer back. Everything was before the Vestry now, and it was the duty of the Vestry to vote on the motion at once. One hundred arc lights would light seven miles of streets, and he suggested Westbourne-grove and Harrow-road first, as the best streets, also Eastbourne-terrace, Westbourne-terrace, and from Royal Oak to Lock Hospital, and from Porchester-street to Westbourne-grove. The 20,000 incandescent lights and 100 arc lights he proposed would cost annually about £17,000, including everything, interest and depreciation of stock, &c. Mr. Minchin had no hesitation in saying that public lighting was impossible if handed over to the companies, their charges being actually prohibitive, and he asked the Vestry as a public duty to take it up themselves. If the Vestry took it up he maintained that in a few years the whole of the streets of Paddington would be lighted with electricity from the profit to be derived from the sale of energy. He agreed that the electric light was a luxury, and he agreed that it would not be right to charge the ratepayers with a high rate for such a luxury, but what he proposed would militate against this. The £50,000 could be raised on loan, and would cost the parish only ½d. rate further on the lighting rate. This would give the electric light under his scheme. He asked them to rise to the heights of the present opportunities. A company would take at least a year before completing, whereas the Vestry could get a Provisional Order before December, and in six months have the light going. Mr. Minchin then moved the motion standing in his name.

Mr. JUDGE said he would not introduce details or the merits of the various professional men whose opinions had been quoted. He proposed to add to his amendment to the effect that the Local Authority, if it desires, be able to purchase the concern at a term of 21, 31, or 42 years. In his opinion, if the Vestry wanted to get the best out of any work it must have private enterprise. The Vestry has all the chances of success and avoids those of failure if it retains to itself the power of purchase at the expiration of a number of years. He advocated two separate systems. If one went wrong the other could be depended upon. He should advise the Vestry to get a definite specification and let the firms estimate for that with sealed tenders, and not have some firms represented before the Committee by an expert. Mr. Judge then moved his motion as an amendment.

Mr. Judge having, at the request of the Vestry, previously withdrawn all the words after "Local Authority," thus leaving the length of time at which the Vestry should have power to purchase open, his amendment was put to the Vestry, when there were 24 to support and 6 against, Mr. Minchin's proposal being lost.

The special meeting then adjourned to Thursday, the 3rd of October.

"THE DANGERS OF ELECTRICITY."

The following letter from Mr. W. H. Preece appeared in the *Times* of Tuesday :—

"SIR : I have read a great many wonderful criticisms of what I am supposed to have said at Newcastle on the dangers of electric currents, but I have not yet read one on what I really did say.* I certainly did not say that alternate currents of high pressure were not dangerous to life, nor that wires conveying such currents may be handled with perfect safety, nor that deaths due to shocks received from electric light wires have been found on investigation to be nonsense ; what I did characterise as absolute nonsense was the reason a mining engineer adduced against using electric currents for the transmission of power in mines—viz., that a man who touched such a wire would be killed. Such currents are invariably direct currents of low pressure, and are therefore quite safe.

I also questioned the propriety of employing electricity for executing criminals, and I intended, as the writer of your admirable summary of the work of the British Association said, to throw 'grave doubts on the invariable certainty of death even from a powerful discharge of electricity.' In fact, no one can yet determine the current which will infallibly kill a man without torture.

I also referred to the propensity of newspaper correspondents to rush into conclusions at once that electric light currents were the sole cause of death, by adducing, amongst others, the Brighton case, where grave doubts as to the cause of death exist—doubts that are amply confirmed by Dr. Whittington-Lowe's letter, published by you on the 19th inst. It was a mistake to couple Major Cardew's name with the conclusion arrived at as to the stoppage of the current. The information on which I spoke was given to me by the local manager of the Electric Light Company.

I have already received a shock of 2,000 volts, and one of even greater voltage, for once I accidentally discharged a Leyden jar through my body, and I have not the slightest desire to repeat the experiment. I am far from underrating the dangers of electric currents, and it is surprising that some of my critics should think otherwise, when they know the active part I have taken in preparing rules and regulations for protection from fire and to person. In fact, I have acted as Chairman of three committees dealing with those questions.

The principal object of my remarks upon alternate currents was to emphasise the advisability of employing safety devices, such as the one described by Mr. Killingworth Hedges, which was the object under discussion. The result of experience is conclusive that electricity with proper precautions can be made safe, both from fire and death.

Every accident due to electric light wires, unfortunately too numerous, with which I am acquainted has been traced to stupidity, ignorance, or carelessness, sources of danger much more prevalent with gas and steam than with electricity, and every one remediable and provided against in regulations extant, but neglected.

It cannot be too strongly urged that the great sources of danger in electric light wires are bad material, inexperienced workmen, neglect of rules, and imperfect inspection. Cheap work in electric light equipments is not only nasty, but very dangerous."

*[What Mr. Preece "really did say" may be found in our report of the discussion on Mr. Killingworth Hedges' Paper in another column of this issue.—ED. *E.*]

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

September 16, 1889.

14,551. H. A. HENDERSON. Manchester. A primary battery solution.

14,552. H. A. HENDERSON. Manchester. Improvements in or relating to primary batteries.

14,565. G. DRAPER and W. H. ASH. London. Improvements in the method of and apparatus for recording telegraphic or other signs, more especially applicable to syphon recorder telegraphic instruments.

14,571. A. P. LUNDBERG. London. Improvements in electrical switches.

14,589. F. H. W. HIGGINS. London. Improvements in printing telegraphs.

14,590. H. GROVES and J. H. STEWART. London. Improvements in electric bells.

September 17, 1889.

14,593. H. F. CAMPBELL. London. Improvements in metallic circuits or conductors of electrical energy.

14,601. G. MACAULAY-CRUIKSHANK. Glasgow. An improved connector for the elements of electric batteries (S. H. Barrett, Massachusetts).

14,636. G. FLETCHER. Derby. Improvements in apparatus for the automatic control and regulation of electrical currents for electric lighting and other purposes.

14,649. W. R. LAKE. London. An improved covering for steam pipes, electrical wires, and the like (C. T. Lee, United States).

14,656. A. BERNSTEIN. London. Improvements in electric glow lamps.

14,666. J. W. RENO. London. Improvements in electric conduits for street railways.

14,677. R. R. MOFFATT. London. Improvements relating to the application and utilisation of electro-magnetism for the separation of metals and to the apparatus therefor.

September 18, 1889.

14,684. H. P. NICHOLAS. Beckenham. Electrical advertisement moving machine.

14,711. T. G. TAGG. London. Improvements in the equipment of craft driven by electricity or any agency other than fluid pressure.

September 19, 1889.

14,780. G. TOYE. Hendon. Improvements in the construction of body batteries for curative purposes.

14,783. W. MEISSNER. London. Distribution of the electric current and the current absorbers in installations with multiple conductors.

The Direct Spanish Telegraph Company.

The following is the report and accounts of the Directors of this Company for the half-year ended June 30th last, to be presented at the general meeting of shareholders to be held on Tuesday, October 1st, at Winchester House, 50, Old Broad-street, E.C., at one o'clock :—

1. The accounts for the half-year ended June 30th, 1889, show, after providing for debenture interest, a balance to the credit of profit and loss of £5,300. 0s. 7d.

2. The traffic receipts are in excess of those for any half-year since the formation of the Company, and show an increase of £508. 6s. 10d., as compared with the corresponding half-year of 1888.

3. The working expenses are £4. 16s. 4d. less than in the corresponding period of last year.

4. With the exception of the interruption of the Bilbao cable from the 11th to the 27th January, referred to in the last report of the Directors, the Company's cables and the land-lines in connection with them have continued in good working order. The cost of the repairs of the Bilbao cable have, as intimated in the same report, been paid, partly out of the reserve fund and partly out of revenue, in the following proportions :—£1,500 from the reserve fund, and the balance (£1,442. 9s. 2d.) out of revenue.

5. The Directors have put £2,500 of the balance of profit and loss to the reserve fund, which now amounts to £14,837. 19s. 10d., and there remains an available balance of £2,800. 0s. 7d. Out of this amount the Directors recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend at the rate of 5 per cent. per annum (free of income-tax) on the ordinary shares, carrying forward £44. 8s. 7d. to next account. The dividend warrants will be issued on October 1st.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended September 13, 1889, amounted to £2,270, and for the week ended September 20, to £3,170.

CHAS. MACINTOSH AND COMPANY (LIMITED).—This company was registered on the 12th inst. with a capital of £300,000, in 2,000 preference and 4,000 ordinary £50 shares, to acquire the goodwill of the business of india-rubber manufacturers, merchants, and commission agents, and other businesses auxiliary thereto, carried on under the style of "Charles Macintosh and Company," at Manchester, London, Liverpool, and Glasgow. Registered office, Cambridge-street Works, Chorlton-upon-Medlock, Manchester.

EASTERN EXTENSION TELEGRAPH COMPANY.—A dividend of 2s. 6d. per share for the quarter ended June 30 last has been declared by the Eastern Extension, Australasia and China Telegraph Company (Limited), payable on the 15th proximo ; and after charging £50,000 against revenue on account of the Western Australian cable, a balance of £26,236 will remain to be carried forward.

REUTER'S TELEGRAM COMPANY (LIMITED).—At a board meeting held on Wednesday, the directors of this company declared an interim dividend at the rate of 5 per cent. per annum, free of income-tax, for the half-year ended the 30th June last, payable on the 12th proximo.

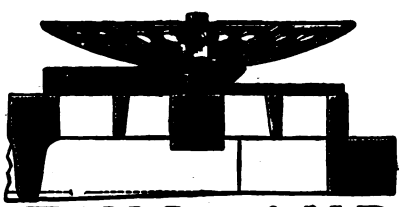
WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended September 13, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £1,128, and for the week ended September 20, £2,071.

BUSINESS CHANGES.—Mr. E. L. Joseph has resigned his position with Mr. Julius Sax, and has joined the firm of Messrs. Appleton, Burbey and Williamson, as traveller.

CHANGE OF ADDRESS.—The offices of the Montevideo Gas Company (Limited), have been removed from 103, Gresham House, Old Broad-street, E.C., to Suffolk House, Laurence Pountney Hill Cannon-street, London, E.C.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 594.—Vol. XXIII. FRIDAY, OCTOBER 4, 1889. Price Fourpence.

NOTES.

In another column will be found the list of awards to the English firms who exhibited at the Paris Exhibition in Class 62 (Electricity). Considering that the exhibitors only numbered 18, it is very creditable that no less than 14 awards were made. This is a slightly higher average than that attained by the 291 French electrical firms, who between them obtained 210 awards, including 6 grand prizes; and it is a much higher average than that attained by the 33 American exhibitors, who were granted 19 awards, including no less than 4 grand prizes. The Silver Medal awarded to the Electrical Power Storage Company was for the E.P.S. system of public supply of electricity devised by Mr. King, and now at work in Chelsea. Woodhouse and Rawson United (Limited), who did not exhibit in the British Section, were granted a bronze medal for the exhibits of their French branch.

The announcement that the London Electric Supply Corporation had commenced lighting operations on a practical scale from their Deptford station on Tuesday last is, we learn, premature. Nothing has up to the present been done from Deptford, beyond a little experimental lighting at the offices of the Corporation at Adelphi-terrace. In the course of a few days, however, the Grosvenor Gallery station will be relieved of a large portion of its load, though, until the mains which are being specially made for the Corporation are completed, it is not deemed advisable to exceed a pressure of 5,000 volts. It is this, no doubt, which gave rise to the rumour that the Corporation intended permanently to reduce the primary potential from 10,000 to 5,000 volts, which, as we stated some time since, is not the case. Considering how much depends on the success of the Deptford scheme, we are not at all sorry to see that the London Electric Supply Corporation have no intention of starting work until everything is really ready.

The Metropolitan Company has for some days been supplying current to the Gaiety Theatre from its station in Sardinia-street. This company, it will be remembered, has also for some time been supplying current to the Garrick Theatre.

The visit of Edison to this country, combined with the greater visibility of the operations of the metropolitan electric lighting companies and the approach of winter, have induced the daily press to devote a considerable amount of its space to electric lighting matters, with the natural result that the public has been regaled with some facts and much fiction. One satisfactory feature of this revival of interest in electric lighting is the rise in the price of the shares of the leading supply companies. Both Brush and Edison-Swan shares have, we are glad to see, participated in this upward movement.

In another column we reprint from the *Journal* of the Society of Arts the practical directions recently given by Mr. Vernon Boys for mounting needles, or mirrors, &c., with quartz fibres. Seeing that the fibre itself is so small as to be invisible, the operation is naturally one which requires some little dexterity, but the method described by Mr. Boys leaves one under the impression that, on the whole, it must be a less difficult and a much less tedious process than that of mounting a cocoon fibre. The immense superiority of the quartz thread is now so well understood that it would be waste of time to recapitulate its advantages in detail, and now that the method of manipulating the fibres has been made clear we may expect a general sweeping away of cocoon threads from our physical laboratories. This step will be rendered the easier by the fact that Mr. Boys has generously refrained from patenting his very beautiful discovery. We understand that one at least of the best-known instrument makers is now supplying apparatus with quartz suspension on demand.

Our New York correspondent sends us some account of an alternate-current motor devised by Lieut. Patten. This machine is identical in principle with the synchronous motor designed at a comparatively early date by Mr. Mordey, and of which some description appeared in our issue of August 9th last. In the Patten motor, however, the two-part commutator of the Mordey machine is not employed, the synchronous reversals of the current in the field-magnet coils being effected by an ingenious method of coupling the armature coils to the commutator. The device can scarcely be made clear without a diagram, which we hope to give next week. This motor must necessarily possess the defects of its type; a commutated alternate current is by no means the equivalent of a continuous current.

The network of inter-urban Telephone lines which has recently been opened by the Postal Telegraph Department in South Wales naturally gives rise to pathetic complaints on the part

Digitized by Google

of the Western Counties and South Wales Telephone Company and their shareholders. This company has laid out a lot of capital in long-distance lines, and although the convenience of immediate communication between Bristol and the South Wales towns is very great, we believe the Company is only now beginning to reap the benefit. We scarcely anticipate, however, that the immediate effect of the Post Office competition will be very severely felt, since the service offered by the latter, though excellent in itself, is much more restricted as to area of communication than that of the Company. On the other hand the Telephone Company makes itself a little ridiculous by assuming a martyr-like air. To hand over 10 per cent. of your gross receipts to your trade rivals is, doubtless, galling; but then it is an old story by this time, and we cannot feel much sympathy with the reiterated complaints which arise wherever the Post Office choose to exercise its uncontested powers.

THE chief importance of the incident, we take it, is as an indication that the POSTMASTER-GENERAL is not wholly oblivious of the fact that by judicious extensions of the existing Postal system it should be possible by-and-bye to reduce somewhat the financial magnitude of the transactions by which the Companies will be ultimately extinguished. It is probably, however, in the North of England, rather than in the West, that such extensions may be looked for. Meanwhile, the simple fact that all Post Office extensions have to be paid for out of revenue, and that the Telegraph revenue is not over-prosperous, may serve to spare the shareholders from undue alarm.

IN connection with our recent visit to the Bradford Central Station, to which we made some allusion last week, a singular thing has since occurred. Mr. SHOOLBRED—at whose invitation we made the journey and who received us with every possible courtesy—was at the time made fully aware of the arrangements we had in view for giving a detailed description of the installation and for illustrating some of its special features. To this he raised no objection whatever, nor is it easy to see what reasonable objection could have been raised. Nevertheless on Monday last we received from Bradford the following communication (to which it will be observed no signature is attached):—

TO THE EDITOR OF THE ELECTRICIAN.

"SIR,—With reference to your recent visit here, we regret very much to have to inform you that Mr. Shoolbred objects to any information or sketch being given other than that which he himself has already supplied.—Yours, &c.,

BRADFORD CORPORATION ELECTRICAL WORKS.

Electric Light Station, Bolton-road, Bradford,
September 28th, 1889."

Now, although in this particular case the matter cannot be regarded very seriously one way or the other, yet we are nevertheless compelled to enter the most emphatic protest against what at least appears to be Mr. SHOOLBRED'S ideas on the duties and privileges of technical journalism. It was open to Mr. SHOOLBRED not to have invited us to visit the station at all; it was also open to him to have requested us to keep silence on any point of detail in which patent rights or other equally cogent reasons might be concerned—that is always well understood—but it is certainly not open to Mr. SHOOLBRED or anyone else, without laying themselves open to possible misconstruction, after having invited a journalist to inspect his work, to object at a subsequent date, and without reason given, to the publication of any other account "than that which he himself has already supplied." It is, of course, a very common thing to receive descriptions of apparatus, or installations, from the makers or contractors, and in inserting such communications it is always made clear that they bear no editorial endorsement, but this is the first occasion within our experience where we have been asked to come and look at a thing and then told, "Now this is what you must say about it, and we object to your saying anything else."

THE City Commissioners of Sewers have met again, and at last their thirst for information has been slaked by a successful motion for the printing of the report of the Streets Committee. Mr. ROSE-INNES was even anxious to have full information with regard to the electric lighting of the City in 1881; but this proposal met with no support. The electric lighting question having thus made some slight progress, the Commissioners immediately adjourned.

THE fact that Mr. GISBERT KAPP has resigned the position of London Editor of *Industries*—which he has filled with conspicuous ability and success since the foundation of that journal some three years since—must necessarily be a matter for regret amongst its wide circle of readers. Mr. KAPP'S retirement has been brought about by the increasing demands upon his time in his capacity as consulting electrical engineer, to which work he intends in future to devote his whole attention. We cannot but feel it to be a matter for congratulation that at a time when there is so much practical work to be done, and so few really qualified men available, an engineer who combines in a peculiar degree theoretical knowledge with practical skill and experience should devote his whole energies to the consulting branch of the profession. Mr. KAPP is succeeded at the office of *Industries*, to a certain extent, at least, by Mr. SWINBURNE, who, we understand, will hold the position of "Electrical Editor"—our readers will agree with us that a better choice could not possibly have been made. Hitherto, however, our contemporary has not devoted a great deal of attention to electrical matters, and we understand that this appointment will not in any way interfere with Mr. SWINBURNE'S existing arrangements.

Electric Lighting in Australia.—Steps are being taken both at Newcastle (New South Wales) and Fitzroy (Victoria) to have the streets lighted by electricity.

Mr. Edison in London.—The name of Mr. J. E. H. Gordon should have been included amongst those present at the dinner given by Sir John Pender last week in honour of Mr. Edison.

Worcester.—At a meeting of the City Council on Tuesday last it was resolved that the Council should apply to the Board of Trade for a Provisional Order authorising them to supply electricity in Worcester.

Blackpool.—The Blackpool Town Council resolved last week that an application should be made for a Provisional Order authorising the Corporation to supply electricity for any public and private purposes in the borough.

Digitized by Google

Waterford.—At the last meeting of the Town Council it was decided to appoint a Special Committee to take the necessary steps to obtain an electric-lighting license, and to oppose the applications from private firms.

Edinburgh.—The Works Committee of the Edinburgh and Leith Gas Commissioners have resolved to recommend the Commissioners to refuse their consent to any of the electric lighting companies obtaining Provisional Orders.

Dundee.—The Special Committee of the Dundee Gas Commission at their last meeting were unanimously of opinion that the Commissioners should acquire power to supply the electric light. A report to this effect will be presented at the next meeting of the Commission.

Leicester.—A special meeting of the Town Council will be held on the 29th inst. to confirm the proceedings of the meeting held on August 27th, when the report of the Gas Committee, recommending that the Corporation should apply for an electric lighting Order, was unanimously agreed to.

Cardiff.—At a meeting of the Electric Lighting Committee of the Cardiff Corporation, held on Monday last, it was resolved that the Council should be recommended to oppose the whole of the applications to be made by the several electric lighting companies for Provisional Orders.

Society of Engineers.—On the 1st inst. a visit was paid by the Society of Engineers to the Central Station of the London Electric Supply Corporation, at Deptford. The company were received and entertained at luncheon by the directors, and were afterwards conducted over the works by Mr. Ferranti.

Aberdeen.—At a meeting of the Gas Committee of the Aberdeen Town Council, held last week, it was agreed to recommend that at the special meeting of the Council to be held on the 7th, to consider the advisability of applying for powers for the lighting of the city by electricity, exclusive powers should be asked for by the Town Council.

Wolverhampton.—At a special meeting of the Town Council to be held on the 31st, the notices of the Wolverhampton Electric Light and Power Company, and the Midland House-to-House Electricity Company, will be considered, and the question of the Corporation undertaking the electric lighting will be discussed.

The Edinburgh Exhibition.—It is announced that the Queen has given her patronage to the Exhibition, and among those who have already agreed to act as patrons may be mentioned the Duke of Buccleuch, the Duke of Sutherland, the Earl of Aberdeen, the Earl of Rosebery, the Earl of Elgin, and the Earl of Kinnoull.

Telephonic and Telegraphic Development in Russia.—According to a correspondent of *The Times*, 500 versts (1 verst = $\frac{2}{3}$ mile) of telephone lines are to be established shortly in European Russia and 100 in Asiatic Russia. To the existing telegraph net there are to be added shortly 1,588 versts in European Russia and 1,421 in Asiatic Russia.

Sale by Tender.—Messrs. Beal, Son and Chartres announce the sale by tender of the lease of the premises at Golden-square, for many years in the occupation of the late Sir Charles Bright, together with the electrical and other instruments, tools, models, &c., and office furniture and effects. Further particulars are given in our advertisement pages. Tenders must be sent in by twelve o'clock on Wednesday, October 16.

Sale by Auction.—Messrs. Wheatley Kirk, Price and Goulty will sell by auction on Tuesday, Wednesday, Thursday and Friday, October 15, 16, 17 and 18, the contents of the works of Messrs. Appleby Brothers, Limited (in liquidation), situate at East Greenwich. Some high-class engines, boilers, machine tools, &c., &c., are included in the sale, further particulars of which will be found in our advertisement columns.

Terni.—The electric lighting of the large steel works at Terni, of which the superficial area is upwards of 2,000,000 square feet, is effected by 100 2,000 candle-power arc lamps and 1,200 75 candle-power incandescent lamps. The current for the arc lamps is supplied by twelve 10 horse-power dynamos driven in pairs by 20 horse-power turbines, the incandescent lamps being supplied by two 75 horse-power dynamos, driven by a 150 horse-power turbine.

Walsall.—At a special meeting of the Walsall Town Council on Monday last week, the Mayor moved the adoption of a recommendation of the Electric Lighting Sub-Committee to the effect that the right to supply electricity should be vested in the Council, and that the Council should make application for a Provisional Order empowering them to supply electricity for public and private purposes within the borough. The recommendation was unanimously agreed to.

The Van Rysselberghe System in Bavaria.—According to the *Centralblatt für Elektrotechnik*, the postal telegraph authorities in Bavaria have declared that the defects in the inter-urban lines established on the Van Rysselberghe system cannot be attributed to the telegraphic apparatus used, but are due to the nature of the system itself. The introduction of the Van Rysselberghe system was, however, vehemently opposed from the beginning by the Government electricians.

Club Lighting.—The new Prince's Club, at Knightsbridge, was lighted by electricity for the first time about a fortnight ago, and the lighting has been pronounced to be a great success. The United Electrical Engineering Company have carried out the work according to the plans of Mr. A. H. Vesey, and the Committee of the Club have requested Mr. Vesey to light the tennis and racquet courts in such a manner that no shadow will be thrown upon the ball during play.

Electrical Engineering Appointments.—Mr. James Raeburn has just been appointed electrician to the Thomson-Houston Company, at Hamburg. Mr. Herbert E. Sturr has also been appointed to the Central Electric Lighting Station at Exeter, and Mr. Arnot has gone to Melbourne to fit up an electric tramway and represent a well-known electrical engineering firm. These gentlemen were all students of the Glasgow and West of Scotland Technical College electrical engineering classes.

Telephonic Development in the West of England.—Steady progress is being made in Torquay and the neighbourhood in the matter of telephonic communication. The number of subscribers to the Torquay Exchange has now reached about 140, and the average daily calls are between 400 and 500. Increasing use is also being made of the telephone in the surrounding towns. Torquay and Plymouth have recently been placed in telephonic communication, and the line is much used.

Obituary.—Mr. C. H. Sharples died suddenly at his residence, Preston, on Sunday, 22nd ult. Mr. Sharples was the junior member of the firm of Sharples and Son, electrical engineers, Fishergate, Preston. He was a Fellow of the Chemical Society and a member of the Institution of Electrical Engineers. He was the first to introduce the telephone into Preston by the establishment of the Preston Telephonic Exchange Company, which, after a few years' existence, was taken over by the Lancashire and Yorkshire Telephone Company.

Calcutta.—We understand, says *Indian Engineering*, that the Government is desirous of introducing the electric light in the Viceregal residence in Calcutta and also in the Lieutenant-Governor's residence, Belvedere, and that several firms have submitted estimates for the work, all of which have proved rather higher than anticipated. The difficulty from the electrical engineer's point of view is that plant and appliances for a full system of lighting have to be provided, although the light is required for only a few months of the year.

Exeter.—The motion for cancelling the permission recently given to the Exeter Electric Light Company to erect overhead wires was rejected at the last meeting of the Town Council by 11 to 25 votes. The Exeter Electric Light Company have successfully installed the electric light at Exeter New Theatre Royal, the installation comprising 450 Edison-Swan lamps of 16-candle power. Over 1,000 lamps have been ordered for private houses, shops, hotels, and public institutions at Exeter, and the company will complete their station next month.

Prize Offered by the Darmstadt Technical College.—The Council of the Darmstadt Technical College have propounded the following question, answers to which will be received up to May 1st, 1890:—The losses which take place in alternate-current transformers consequent upon the heating of the iron are due partly to Foucault currents and partly to molecular friction caused by the changes of magnetism. The influence of each of

Digitized by Google

these two causes on the total loss under various conditions must be determined by experiment. A prize of 150 marks is to be awarded.

Leeds.—The Leeds Borough and County Council decided on Wednesday, after a brief discussion, to postpone the further consideration of the report of the Electric Lighting Committee for six months. As the municipal year closes in November, this decision is equivalent to postponing the subject indefinitely, and the adoption of the amendment to this effect by 28 votes to 17 was practically the abandonment of the scheme, which was presented to the Council on July 3rd, and involved an estimated total capital expenditure of £68,000. (*Electrician*, June 28, p. 189.)

Glasgow.—The draft Provisional Order which it is intended to submit to the Board of Trade, asking powers for the Corporation to supply the electric light in Glasgow, will shortly be laid before the Corporation Gas Committee and the Corporation as a whole. Authority has been given to a special sub-committee to meet and confer with Messrs. Muir, Mavor and Coulson, or any other private firm who may desire to have a conference in view of the Provisional Order being applied for. It is thought that the actual work of generation and distribution will be let out on contract to one or more private firms.

The School of Electrical Engineering and Submarine Telegraphy.—We are informed that, as the result of the examinations for the certificate of the school, recently conducted by Mr. Gisbert Kapp, the following gentlemen have obtained the Certificate in Electric Lighting and Power Transmission :—Messrs. H. E. Bartlett, S. Bone, J. H. Bonwer, jun., J. A. Fraser, W. C. Goodchild. The candidates had to answer two Papers—one in Mechanical and the other in Electrical Engineering—and had also to pass a *viva voce* and practical examination. The minimum required in each Paper was 60 per cent., and for the practical examination 70 per cent.

Cheltenham.—A special meeting of the Cheltenham Town Council is to be held on the 21st to consider whether application shall be made to the Board of Trade for a Provisional Order authorising the Corporation to supply electricity for public and private purposes within the borough. Several electric lighting companies have sent in requests for the consent of the Corporation to the granting of Provisional Orders to them. The Town Council has, it will be remembered, already on more than one occasion decided that the introduction of the electric light was desirable, and that the introduction should be made by the Corporation rather than by a company.

A Large Belt Press.—A few years ago a 36in. or 40in. belt was as large as belt manufacturers were ever called upon to make, but with the growth of the manufacturing industries and the largely-increased size of single establishments, greater power is required than formerly, and belts of greater weight and width are constantly called for. To meet this new demand Fayrer-neath and Ladew, of New York, the manufacturers of the Hoyt leather belting, are erecting a hydraulic press capable of making belts of any width up to 78in. This is said to be the largest belt press that has ever been made, and it will be used first on a 64in. belt which has been ordered from the above-mentioned firm.

Lectures on Dynamo Machines.—We have received the syllabus of the course of twelve practical lectures on dynamos, which will be delivered by Mr. W. B. Esson at the School of Electrical Engineering at Hanover-square. From this we gather that Mr. Esson intends to deal with this important subject in a thorough and comprehensive manner. The best form and material for magnets, the reaction of the armature upon the field-magnets, parasitic currents, methods of armature winding, dynamo testing, dynamo efficiency, self-induction, &c., &c., will all be fully touched upon. This course of lectures will, we are sure, prove of great value to all who wish to obtain sound practical information on the subject of dynamo design.

Postal Telegraph Revenue.—The revenue returns for the quarter ended September 30th continue, so far as relates to the telegraph service, to show a most satisfactory increase. Compared with the September quarter last year there has been an increase of no less than £55,000, and on a comparison of the years ending September, 1888, and September, 1889, the increase amounts to £190,000. The details for the four quarters of the two years are as follows :—

	Dec. 31.	Mar. 31.	June 30.	Sept. 30.	Total.
1888-9.....	£515,000...	£520,000...	£525,000...	£620,000...	£2,180,000
1887-8.....	£465,000...	£480,000...	£480,000...	£565,000...	£1,990,000
Increase ...	£50,000	£40,000	£45,000	£55,000	£190,000

Metallisation in a Vacuum.—The *Revue Internationale de l'Electricité* describes a curious phenomenon recently observed when experimenting with electric discharges *in vacuo*. In a glass tube, 3 centimetres in diameter, from which the air had been exhausted, and containing at either end a platinum or copper electrode, consisting of a wire bent at right angles to itself several times so as to form a series of squares, one within the other, a 30-centimetre spark was passed. The metal was volatilised, and was deposited on the negative pole, taking the shape of the electrode it had left. The image formed by the deposited metal was, however, turned round through an angle of 90deg.

The Great Western Electric Lighting Works.—The following is a copy of a letter which has been sent to the Electric Lighting Committee of the Paddington Vestry :—

"Dear Sir : In your recent report to the Paddington Vestry I observe that you speak of the Great Western Electric Lighting Works having been designed and arranged by Mr. Spagnoletti. I am directed to inform you that the whole of these works were designed and carried out throughout by Mr. J. E. H. Gordon, the Engineer to the Metropolitan Electric Supply Company (Limited) and to the Electric Construction Corporation (Limited). The works were not placed in Mr. Spagnoletti's charge until after they were purchased by the Great Western Railway Company, after more than a year's successful running, and after all difficulties had been overcome.—Yours faithfully, HENRY SINCLAIR."

Moulded Mica Insulators.—We have it on the authority of the *Commercial Advertiser* of New York that a new kind of insulator has just been put upon the market. The substance is known as "lehte," a composition made largely of mica. It has been widely used for the purpose of trolley-line insulators in electric street railways, and has given great satisfaction. In motors it has found a place in commutator brush yokes, which are made entirely of lehte, or of iron with lehte covering. A valuable quality in this insulator is the ease with which it is attached to metal. Used as an insulating covering, or moulded together with metal parts for connection, the union of lehte and metal is so perfect that they cannot be parted, nor is there any possibility of separation by expansion or contraction of metal in change of temperature. While it is not intended for high temperature, lehte bears the greatest cold without becoming brittle, and, being unaffected by weather, it is highly suitable for outside work.

St. Hilaire-du-Harcourt.—The remote town of St. Hilaire-du-Harcourt (Manche) possesses an interesting little electric light installation, which has been running since the beginning of May. The dynamo is situated four kilometres outside the town close to a stream called the Vauroux, the water from which is collected in three ponds and made to drive two 10 horse-power 5 metre water wheels, running at seven revolutions a minute. The dynamo is a 10-unit (600 volts and 17 amperes) Thury machine, running at 800 revolutions. This machine charges three sets of Gadot accumulators, arranged in series at sub-stations in the town. The municipal lighting comprises 80 lamps, which are automatically switched on and off by a clockwork device attached to the Jacquemier coulomb-meter registering the ampere-hours furnished to the accumulators. The price of a 10 candle-power light for private consumers is 5 centimes per lamp per hour. The conductors, which are run overhead, are of bare copper wire.

Sheffield.—At a special meeting of the Sheffield Town Council, held last week, the application of the Sheffield Telephone Exchange and Electric Light Company for the consent of the Corporation to an electric lighting license was considered. The Mayor stated that at a meeting of the Improvement Committee a resolution was carried recommending the Council to send the same answer to this application as was sent to the one from the Electric Construction and Maintenance Company, namely, that

Digitized by Google

the Council will not give their consent to any license or Provisional Order being granted to the company for supplying electricity in Sheffield, on the ground that the Council might probably itself seek to obtain powers necessary for that purpose. The Mayor moved a resolution to this effect, remarking that it was not at present desirable to allow any company to get a footing in Sheffield, because in the course of a very short time they would have to take up the question themselves and deal with it. The resolution was agreed to unanimously.

Stafford.—The Gas Engineer, Mr. J. Ferguson Bell, has presented a lengthy report on the subject of electric lighting to the General Purposes and Gas Committees of the Stafford Corporation. Mr. Bell thinks that it would not be advisable to erect a central station unless there is a probability of a minimum of 2,000 16 candle-power lamps being required within the area of supply. He recommends the adoption of the alternate-current transformer system, and suggests that if the Corporation decide to do the lighting themselves, a start should be made with a 3,000-light plant, to cost, with buildings, mains, &c., £14,500. The charges are to be 7d. per Board of Trade unit, or 40s. per 16 candle-power lamp per annum. Coming to the question of profit, Mr. Bell estimates that if 1,200 lights are taken up at 40s. a light, and allowing for a maximum consumption of current equal to 2,000 hours per lamp per annum, the station would yield a net income of about £200 per annum; if 2,000 lights are taken up, the estimated profit upon the same basis is £1,565.

Electrical Figures drawn by Lightning.—At a recent meeting of the Académie des Sciences, M. Ch. V. Zenger showed two mirrors which had been injured by lightning, and presented some remarkable traces of the discharge. On the 9th of June last a villa at Zehrooice, near Prague, was struck by a fireball, which burst with a formidable noise, piercing the roof and ceilings. The floor of the concierge's lodge was lifted 52 centimetres, and a looking-glass hanging against the wall was struck. The gilt frame of the mirror was damaged in ten places, the gilding being volatilised and deposited on the face of the glass, while on the back the volatilisation of the quicksilver gave rise to most remarkable electrical figures, the appearance of which showed that there had been multiple and successive discharges, as indicated in recent lightning photographs. The second mirror, presented by M. Zenger, was merely a fragment, the mirror having been shivered by lightning in July last while hanging up in the room of the manager of some chemical works at Wolfsschlinge, near Aussig (Bohemia). The fragment was pierced in numerous places, each perforation presenting the appearance of a water spout of molten glass which had suddenly been solidified.

The Lighting of the City.—A special meeting of the Commissioners of Sewers was held on Tuesday last with reference to the subject of electric lighting.—Mr. Sly moved: "That the report of the Streets Committee of July 30th, on electric lighting, and the abstract of tenders be printed and circulated among the members of the Commission."—Mr. Pannell said he did not think it would be any advantage to go back to the original contracts under which the City was more or less efficiently and sufficiently lighted, unless they followed the whole history from that time up to the present. There were a number of reports founded on the efficacy or non-efficacy of electric lighting, but it would be no advantage to have all that before them. The motion was carried.—Mr. Innes said he had no desire to obstruct the electric light. He moved—"That the engineer be requested to supply the names of the companies who lighted the City experimentally some years since, the districts lighted, and the result of the experiments up to the present day. This was negatived.—Mr. Pannell then moved: "That the engineer and Mr. Preece be requested to amend the abstract of tenders so as to make it uniform with the conditions under which the various companies are now prepared to contract. They would then have each of the companies' proposals before them. This was agreed to, and the Commission adjourned.

Birmingham.—It will be remembered that the Birmingham City Council some little time ago passed a resolution withholding consent to the application of Messrs. Chamberlain and Hookham to the Board of Trade for a Provisional Order empowering them to supply electricity for public and private purposes if the larger area outside the central area of the city were insisted on, but authorising the General Purposes Committee to consent to the said Order if the amendments of the Corporation were accepted, subject to such modifications of detail as the Committee or the Board of Trade might deem proper. The General Purposes Committee reported at the last meeting of the Council that after considerable correspondence with the promoters and the Board of Trade on the subject, a new and revised Order was sent to the Town Clerk by the Board of Trade, confining the area to be supplied to that comprised in Schedule A (the central area) as desired by the Corporation, and accepting and adopting a large number of their amendments. The Committee being of opinion that the Corporation amendments not inserted by the Board of Trade were unimportant, they had no hesitation in giving their consent to the Order in its amended form, and accordingly authorised the Town Clerk to affix the Corporate seal thereto, believing that the interests of the Corporation had been protected as far as practicable.

Post Office Telephone Competition.—A notice has been issued by the Postmaster-General to the effect that:—"On and after the 1st October the telephone wires which have been provided by the Post Office between the following towns in South Wales may be used by the public on payment of a fee of 6d. for a conversation not exceeding three minutes: Cardiff, Barry Dock, Newport, Alexandra Dock, Pontypool, Talywain, Briton Ferry, Swansea. Any person joining the telephone exchange of the department in one of these towns can use the wires to the other towns from his own office. Other persons can do so on going to an office of the department where a silence-box has been provided. The local telephone wires in the above-mentioned towns may also be used by the public; the fee for a conversation of not more than three minutes within one and the same town being 3d. Under this arrangement a person whose office is not connected with the local telephone exchange can at any time hold telephonic communication with a person whose office is so connected, on going to one of the offices of the department where a silence-box has been provided for the purpose. The limit of three minutes may be exceeded on payment of 6d. or 3d., as the case may be, for each additional period of three minutes or less." It is also announced that the telephone wires which have been provided by the Post Office between Liverpool and Manchester may be used by the public on payment of the same fee as above.

Method of Taking Photographs of Lightning Flashes.—At a recent meeting of the English Photographic Club, Mr. W. Marriott was requested to draw up instructions for taking photographs of lightning. The following brief rules are offered:—1. The camera should be focussed during the daytime to some distant object and a mark made on the camera, so that at night it may be quickly adjusted when a storm is approaching. 2. A rapid rectilinear lens, with full aperture, should be used. 3. The camera should be directed to the part of the sky where the lightning is most likely to occur. 4. The camera should be firmly screwed to the tripod stand. 5. It may be necessary to tilt the camera slightly, especially if the lightning be mostly in the zenith. If this be done, a note should be made of the amount of inclination. 6. A portion of landscape, roof, chimney-pot, &c., should, if possible, be included on the plate. If this cannot be done, the top of the plate should be carefully marked before it is removed from the dark slide. 7. The exact time of each flash, the interval in seconds between the lightning and the thunder, and the point of the compass in which the flash appeared, should all be carefully recorded. 8. It is desirable that there should be only one flash upon each plate. 9. If circumstances permit, two cameras should be used—one fixed on the tripod stand and the other held in the hand—and two separate photographs obtained of the same flash. 10. It would be very interesting and valuable if two or more photographers could obtain pictures of the same flash from different points of view. By this means it might be possible to determine accurately the distance of the flash, and also its movements in the atmosphere.

SKETCH OF THE ELECTRICAL PAPERS IN SECTION A

READ BEFORE THE BRITISH ASSOCIATION AT NEWCASTLE.

BY DR. OLIVER LODGE.

Not a brilliant meeting so far as mathematics and physics are concerned, the most important Papers communicated to Section A at Newcastle lie outside the range of electrical science, and hence our notice this year may be brief. The distinction between Electricity and the rest of Physics is an arbitrary and unsatisfactory one, and it may be permissible, even in an Electrical Journal, to mention that the communications most interesting to physicists were one on "The Extensibility of Liquid Films," by Lord Rayleigh, and one on "Boscovich's Theory," by Sir W. Thomson.

The first was full of acute observations, based partly on a view of Marengoni regarding the cause of the permanence of liquid films in certain cases and their evanescence in other cases, and for the first time some distinct notion of the reason of the steady existence of a soap-bubble—that long-standing puzzle to physicists, began to be formed in the minds of those present. The Paper marks a very distinct step in advance in our knowledge of the mechanics and structure of soap-films.

The other communication I have referred to, that on Boscovich's theory, might have been called the Mechanics of Crystallography, or Molecular Statics. It was a powerful and acute piece of pure mechanical reasoning, showing how a great number of the extraordinary behaviour of crystals, including some only recently discovered, and some which at first hearing seem quite incredible, can be accounted for by imagining the molecules built up according to a certain law of force between the parts, a force attractive at some distances, repulsive at others, and not specially contemplating or troubling about how the forces arise, nor of what the substance of the molecules is composed—treating them, in fact, as abstract centres of force (which they certainly are, however much else they also be) and ignoring their inertia, very much as Boscovich in his century-old memoir did. Crystals of various orders, hemihedral crystals, crystals with a periodic structure, and consequent curious selective reflexion for light, crystals that can be sheared, and molecules that are liable to fly to pieces and detonate, were all referred to, and models built up of spiral springs were used to illustrate them.

Taking now the Electrical Papers in order, we find first a preliminary account of a determination of "v," the velocity of electro-magnetic radiation, made by the writer and Mr. Glazebrook by means of the oscillating discharge of a Leyden jar. The method consists in taking an air-condenser of measurable capacity, discharging it across a pair of knobs through a circuit of measurable self-induction, and observing the rate of oscillation during the discharge by photographing the spark on a sensitive plate kept whirling at a known number of revolutions per second. The record on the plate is afterwards examined micrometrically, and the arc occupied by an electric oscillation accurately determined. In the final series of measurements the condenser was built of 11 plates of plate glass cut 2ft. square, silvered on both sides, and set up parallel to one another, with an air space of half a centimetre separating adjacent surfaces. The capacity of this condenser was about 60 metres in electrostatic measure. The discharge circuit consisted of about three miles of No. 22 india-rubber covered copper wire, carefully wound into a regular coil 11in. inside, 19in. outside diameter, and 4in. thick. The self-induction of the coil was $4\frac{1}{2}$ quadrants (or secohms) in electro-magnetic measure. The spark occurred between two small knobs, about a millimetre or so apart, and the charging was done by means of an ordinary Voss machine, half connected half disconnected by means of a needle-point arranged to give a brush discharge across an inch of air into one coating of the condenser; the other coating, consisting of the two outside and the other alternate plates, being earthed.

The photographic disk, on which the spark record was obtained by means of a quartz lens focussing the spark knobs upon it, was pivoted on an axis perpendicular to its plane and spun by means of a turbine (a Bailey "Thirlmere" water motor) 64 turns a second. The speed of the disc was measured and kept constant by the same device as that used by Lord Rayleigh in his classical determination of the ohm, viz., a stroboscopic card attached to the axis of the disc and watched between the jaws of a vibrating tuning-fork. The fork being set accurately to vibrate 256 times a second, a four-rayed star pattern on the card was kept optically stationary by the observer letting the driving string pass through his fingers and tightening or slackening his grip of it as required.

Under these circumstances the spark image on the plate is drawn out into a long-beaded band or circular arc, each bead of which corresponds to a semi-oscillation. With the dimensions above specified each bead occupied an arc of about 13deg., and there were 8 or 10 of them visible for each spark. In this way a record of about 30 sparks in eight concentric circles were obtained on each plate, and dozens of plates were filled. The plates were Messrs. Mawson and Swan's most highly sensitive, 4in. square, and were kindly sent for the purpose by Mr. J. W. Swan.

The calculations are not yet completed, but the value of "v" is coming out of the same order of magnitude as that obtained by other and simpler methods.

Prof. Ewing's Paper on "Magnetic Viscosity in Iron" has to do with the effects of very small magnetising forces applied for a long time. He finds that iron does not behave as a rigid body to these forces, but that there is a slow viscous yielding or development of magnetisation, which as slowly subsides when the force is withdrawn.

The magnetic behaviour of iron is therefore quite analogous to the mechanical behaviour of an elastic solid possessing a trace of plasticity, partly obeying variations of force instantaneously, and partly yielding continuously to a force kept steadily applied for a long time. Of course all this viscous yielding is accompanied by dissipation of energy and production of heat. The effect had been observed by Prof. Ewing before, but he now measures it carefully and goes into much detail regarding it.

On Monday were read a few Papers on "Atmospheric Electricity."

Prof. Michie Smith described the observations he had made in India with a Thomson portable electrometer, and related the manner in which he had succeeded in getting the instrument to work, notwithstanding the damp tropical heat. It was done by taking extra precaution about the drying acid inside, by charging with a machine instead of with the customary electrophorus, and by having the insulation of the charging rod too hot to touch. In fine weather, though the potential of the air was, as as usual, positive, he found a cloud of dust gave distinct negative indications. This observation was explained by Sir William Thomson, in the simplest manner, by the statement that in fine weather the upper regions of the atmosphere were positively electrified, and the earth's surface negative, while the potential of the air was everywhere positive, gradually increasing upward from zero at the earth surface to a high value. This being the normal state of things, a cloud of dust, or anything else blown from the surface of the earth, would naturally be found with a negative charge after the fashion of a proof-plane.

Prof. L. Weber sent some photographs of lightning taken in a camera moved elliptically by hand. This mode of motion scarcely gave so simple an analysis of the flashes as the simple lateral motion employed by Dr. Hoffert, but, just as in his case, some flashes were analysed into several intermittent discharges connected by a luminous glow or aureole of phosphorescent air. Flashes thus analysable are really a succession of rapid spits, such as can be obtained in the laboratory through a very high resistance, and they last an appreciable time. It is probable that they are not the sudden and violent kind of flash.

Mr. Clayden described again his experiments on obtaining dark flashes from a Wimshurst machine on photographic plates, and showed that these dark appearances were matters of photography and developing, and accordingly were of chemical not physical interest. In this statement he had the concurrence of the President (Captain Abney).

A Paper by Messrs. Maclean and Makita Goto described some experiments on the electrification of air by ordinary combustion. It was found that burning charcoal electrified the air negatively, while burning phosphorus and most other things electrified it positively. It is to be supposed that the electrification observed belongs really to smoke particles and not to the air itself, since it is not likely that air itself can be charged, but the fact that some atmospheric electrification can be certainly produced by combustion may possibly have an important meteorological bearing.

Coming now to Tuesday, a considerable number of electrical Papers were rapidly gone through. The Electrical Standards Committee reported in favour of adopting Mr. Heaviside's term "impedance" for the ratio of an averaged electromotive force to an averaged current. *Spurious resistance* is the only other term that suggests itself, and it is a pity the French Congress did not decide on this in preference to "apparent resistance." "Fictive" is a term more correctly applicable than "apparent," for, as Lord Rayleigh said, the identity of impedance with resistance is only "apparent" if you shut your eyes. The term resistance will remain defined, in accordance with Joule's law, as the ratio of the energy dissipated per second to the mean square of current. The resistance thus defined is by no means independent of the effects of self-induction in the case of rapidly alternating currents. The choking or throttling of the conductor by concentration of current to the periphery forms part of this true resistance, but no mere inertia-like or massive obstruction without frictional dissipation is included in it. Every kind of obstruction is lumped together in the idea connoted by impedance; the term resistance is limited to frictional or irreversible obstruction. For steady or slowly-varying currents in homogeneous circuits the two coincide.

It may be helpful to remark that impedance and resistance of every kind are all quite properly expressible in ohms; hence the sometimes-employed term "ohmic resistance" is not really discriminative.

Most of the resolutions adopted by the Paris Congress could be re-adopted by the Standards Committee with satisfaction; but on one point there was some discussion, viz., with respect to the name for the unit coefficient of electro-magnetic induction. The rather barbarous name "secohm" has never been quite heartily received, though it is unobjectionable in every scientific respect; the name "quadrant" now adopted, although in the electro-magnetic system of units the quite natural and simple statement for a thing of the dimension of a length, and a length approximately equal to the Earth's quadrant, yet has the disadvantage of always entailing the appendage, on occasions when one wishes to be exact, of the words "in electro-magnetic measure."

Those who feel, like the writer, that the artificial electro-magnetic and electrostatic systems are both doomed to leisurely extinction in the course of the next few decades may experience some regret that a name so manifestly signifying a length should be thus introduced for a quantity which is not a length at all, and which is only the dimension of a length on a conventional system of units.

No such objection applies to the word "ohm" or its derivatives; for though it is sometimes asserted that an ohm is a velocity, by those who ignore the fact that it is only a velocity on a conventional system, yet nothing of the kind is connoted by the term; and the ohm as a practical unit of resistance may last for ever. However, so long as it be clearly recognised that the quadrant is merely the *electro-magnetic* unit of self-induction, and that not except thus conventionally is self-induction a length any more than resistance is a velocity, so long the term may be accepted as, perhaps, on the whole, the most convenient for temporary and terrestrial use.

Mr. Shaw communicated the first part of his report on Electrolysis, the gist of which mainly was that Ohm's law, Joule's law, and Faraday's law were the fundamental facts on which there seemed to be no legitimate difference of opinion, and which might be taken now as well established for many electrolytes, if not for all. It is as soon as one steps beyond the ground covered by these laws that debateable points begin to bristle on every side.

Prof. Worthington transmitted as part of the report of the Electrolysis Committee an account of some simple and interesting experiments he had made on the well-known discharging power, over electrified bodies brought near them, which flames possess. Several of these experiments suggest an electrolytic cause for this effect; dissociated and charged atoms being either drawn out of the flame on to the surface of the charged rod, or else the charge of such atoms is passed on to the rod by a sort of Grotthus chain set up in the air, the atoms themselves remaining behind. The former is the more natural idea, considering that air is not an electrolyte, but Mr. Worthington was impelled to the other, or Grotthus chain view, by the experiment of enveloping the charged rod in a blast of air, and perceiving that the action went on just as well through the blast. It was felt, however, by the Section that though such a blast might curve the paths, yet it need not stop the progress, of the charged atoms; and that their speed through air was likely to be greater than that of any easily practicable blast. Several of the experiments devised and quoted by Worthington are capable of easy and instructive repetition, however they be ultimately explained.

A most interesting communication from Prof. Schuster followed, with reference to the phenomena occurring in a vacuum tube, especially in the neighbourhood of the negative electrode. It has been long known and emphasised in Mr. Crookes' researches that electricity is conveyed in such tubes by a torrent of charged atoms driven in straight lines by electric forces with great speed from the negative electrode, the convection of such charges constituting a true current, capable, for instance, of being deflected by a magnet, and the impact of the atoms themselves being able to drive windmills as well as to raise matter to incandescence. Prof. Schuster now makes an attempt to measure the speed of this torrent of atoms by immersing them in a uniform magnetic field and observing the curvature of their path. He concludes that their speed is gradually reduced by collision until one of the stratifications or luminous layers is reached, when the collisions are so numerous that they are reduced to comparative rest, and the energy of their translation is transmuted into vibratory energy and radiation. He also, by means of tapping ring electrodes, succeeds in measuring the fall of potential along the tube, and shows that the great step of potential occurs close to the negative electrode, whence the torrent of negatively-charged atoms is impelled. A crowd of positive atoms await them across the interval of the well-known and remarkable "dark space."

The stratification layers in a vacuum tube are produced by an effect analogous to that which produces the ripple mark in tidal sand and the bars at the mouth of tidal rivers—so said Sir William Thomson; vaguely we have long supposed that the strata were regions of collision, and that the intervals between corresponded to free path, but we are now evidently getting nearer to a clear mechanical understanding of the processes, occurring in a vacuum tube, and of the discharge of electricity through gases, as a simple result of the presence of crowds of freely-moving charged atoms subject to ordinary electrostatic and mechanical laws.

After this the writer gave a hasty account of some experiments made in his laboratory on the effect of Metal Screens in warding off the quasi-electrostatic action of moving or varying charges. So long as a charged body is stationary, the thinnest film of conductor is of course perfectly effective in screening off the whole of its lines of force and forming a perfect electrostatic shadow in the interior of a closed space surrounded by it, but whether a bird-cage or tinfoil screen would be as effective for violently moving or varying charges was the thing investigated. It was found that so long as the walls were of ordinary thickness a gauze house or silver-coated beaker was completely impervious to any perceptible disturbance from without, the disturbance looked for being either a microscopic spark or else the microscopic deflection of a very light "needle," highly charged, positive at one end negative at the other.

But by coating beakers with thinner and thinner films of silver until the resistance of the coat increased from a fraction of an ohm to something like 70 or 100 ohms, a distinct deflection of the needle inside could be observed when a charged body was rapidly moved outside, or when a charged sphere outside

Digitized by Google

was suddenly discharged. And when the film had as high a resistance as 1,000 ohms some metrical results were obtained. But all the films that thus permitted electrostatic actions* to penetrate them could also be seen through; and directly the film was thick enough to be opaque to light no perceptible trace of electric action could be got through it whatever was done to charged bodies outside. Doubtless there is a quantitative relation not expressible without regard to the violence of the original disturbance, and the phrase "opaque to light" is vague and not strictly defined, but such in general terms is the preliminary result arrived at.

Prof. Perry exhibited a variable standard of self-induction in a form which he proposes to issue for laboratory use, and which is likely to prove of great convenience. It is merely a pair of coils, one fixed, the other movable round an axis inside the fixed coil, so that it may be at any angle with its plane. The self-induction of the whole is composed of the self-induction of each coil separately, plus or minus twice the mutual induction of one or the other, according as they are turned to oppose or to help their separate actions. Such an instrument, in rude form, was already used by Lord Rayleigh, and its principle of graduation investigated by him theoretically.

It is not to be understood as a self-induction *meter*, but as a variable unit; bearing, in fact, the same relation to self-induction as a graduated rheostat does to resistance, but being likely to be a more reliable and satisfactory instrument than a rheostat, in that it is free from the defects of variable contact.

The defect at present of Prof. Perry's instrument seems to be its comparatively small range. It may be possible to increase this by having many coils instead of only two, though the plan of graduation to be adopted in such a case is by no means obvious at first sight. One might suggest that the various coils should be so connected with cogged wheels as to move from perfect discordance to perfect accordance in a regular and systematic manner when a handle is turned over a graduated spiral dial.

Mr. Preece described some experiments which he had instituted with the object of proving to himself and others that the theoretically predicted throttling by concentration of current to the periphery of conductors did really occur in actual practice with commercial alternating currents. The method adopted was to observe the elongation through rise of temperature of a number of conductors of different material (especially copper and iron) when powerful alternating currents were sent through them. Naturally, those that most obstructed the current would get hottest and so elongate most. Various frequencies were tried, and, as was to be expected, iron tended to heat abnormally much for high frequencies. Part of this is due to hysteresis, but another part is due to throttling. At immensely high frequencies theory asserts that all the heating will be due to throttling and none to hysteresis; at very low frequencies such extra heating as there may be will be due to hysteresis. At intermediate frequencies the two effects will be mixed up. The plan of observing expansion would not have struck one as satisfactory at first sight, for many reasons, but the results obtained seem to justify the method from a practical point of view.

Prof. H. Stroud described the result of some attempts he had made to obtain simple and direct evidence of the "Thomson effect" in copper and iron, by looking for an E.M.F. at the junction of hot and cold pieces of the same metal. He imagined that he had got the effect, but it is not at all clear to the writer how it can possibly be so. Prof. Stroud would admit that the Thomson E.M.F. does not depend on the steepness of the gradient of temperature, and that in a closed homogeneous circuit of non-uniform temperature the Thomson effects must therefore balance one another; how then can he hope to get a result by merely introducing a cut place with a violent step of temperature carefully maintained there? That he does get a result must be supposed due to some spurious or disturbing cause, unless evidence, not known to the writer, is forthcoming.

The curious photographic effect brought forward by Mr. P. Braham, as due to the action of a magnet's poles on a dry plate, was not regarded as proven by those in the Section most competent to judge. Such an action would be most interesting if established, but great care must be taken to be sure that no similar markings were on the plate before exposure to the magnetic field.

Few of the remaining Papers call for special mention; some of them had been published before. Prof. Blyth exhibited a current-weigher on the plan of an ordinary letter-balance. Prof. Silvanus Thompson projected on the screen the already well-known obstruction by crust of copper oxide when a current too intense for size of anode is sent through a copper voltameter. Mr. Swan described the use of chromic acid in preference to nitric acid in batteries. Prof. Perry described a future voltmeter on the plan of his beautiful spiral springs—an instrument of which we shall, of course, hear through other channels—and Mr. Bottomley exhibited his very interesting collection of cracked Leyden jars, already partially described, with comments by the present writer and by Mr. Boys, in *The Electrician* for March 29 and April 5 of this year.

* They cannot properly be called electrostatic actions—they are essentially electro-magnetic, but it is misleading to use either term in such a case.

THE ELECTROMOTIVE FORCES PRODUCED BY THE CONTACT OF SIMILAR METALS AT DIFFERENT TEMPERATURES.

BY SHELFORD BIDWELL, F.R.S.

In connection with the Paper read by Prof. H. Stroud at the recent meeting of the British Association (*The Electrician*, Sept. 27, p. 519), it may be of interest to give a short account of some hitherto unpublished experiments which were made by myself five years ago in the hope of throwing some light upon the nature of the electromotive forces set up when hot and cold wires of the same metal are made to touch each other.

In the first place, I convinced myself (rightly or wrongly) that the thermoelectric forces in question were not connected, at least in any direct and simple manner, with the electromotive force of the Thomson effect. This conclusion was arrived at mainly by consideration of the fact that when the hot and cold wires (or rods or tubes) are brought into actual contact, there cannot be any real breach of continuity in the fall of the temperature on either side of the maximum. The slope on one side may, indeed, be very steep, but it will never be an absolutely perpendicular precipice. Between the points of highest and lowest temperature there must necessarily be points at which every intermediate degree of temperature is represented in continuous succession; and, if this is so, then it seems clear that there must be *two* Thomson electromotive forces of equal strength, both of which act either towards or from the point of maximum temperature (according to the metal), and accurately balance one another. Thus no current at all can be started in the circuit by their agency.

A number of experiments made with iron, platinum, German silver, cadmium, zinc, silver, gold, copper, lead, tin, nickel and palladium confirmed this view. They, at all events, disclosed no correspondence of a simple nature between the Thomson effect and the direction of the observed currents, as will be seen by reference to the first three columns of the annexed table in which the results are given:—

Metals.	Thomson Effect.	Contact current. Hot to cold = +, Cold to hot = -	Thermo-currents.		
			Unstretched to stretched = +. Stretched to unstretch'd = -	Hammered to unhammered = +. Unhammered to hammered = -.	Unannealed to annealed = +. Annealed to unannealed = -
Iron	-	-	+	+	-
Platinum	-	+	-	-	-
German Silver.	-	+	-	+	+
Cadmium	+	+	+	-	-
Zinc	+	+	+	-	-
Silver	+	-	-	-	-
Gold	+	-	-	-	-
Copper	+	-	-	-	-
Lead	0	0	0	0	0
Tin	+	+	-	+	-
Nickel	-	+	-	-	-

Digitized by Google

The experiments were in every case repeated many times, and several different specimens of the metals were generally used. Special precautions were also taken to guard against errors resulting from oxidation.

The Table indicates a material point of difference between my results and those of Prof. Stroud. I found that in the case of copper, the current always passed from cold to hot through the junction, while, according to Prof. Stroud, it passes from hot to cold. While writing this Paper I have again tried the experiment with a new specimen of high-conductivity copper wire, and the current was clearly and unmistakably from cold to hot, as before. I will not attempt to conjecture the cause of this discrepancy.

As regards iron we are in agreement. With every specimen of wire that I used, whether thick or thin, annealed, hammered, or stretched, the current was always from cold to hot through the junction.

There is yet another point on which I venture to differ from Prof. Stroud. He says in his Paper (p. 520) with reference to the thermo-electric diagram, Fig. 1, which is here reproduced, "If copper kept at a high temperature indicated by position A in the diagram is placed in contact with an identical copper conductor kept at a low temperature, indicated by say, position B, we should, it seems to me, expect an E.M.F. to be established from hot to cold, seeing that the Thomson effect in copper is positive; or, in other words, since an electric current flowing through a copper conductor, in which there is a gradual fall of temperature in the direction of the current, has the effect of reducing the differences of temperature, we should expect the contact of hot and cold copper to give rise to an E.M.F. which would be in such a direction as to tend to reduce the difference of temperature, *i.e.*, from hot to cold."

I think there is a little misunderstanding here. The arrangement is not at all analogous to a bismuth-antimony circle, in which a current flowing in a certain definite direction would tend to equalise the temperature of two unequally heated junctions, by cooling one of them and warming the other. It is

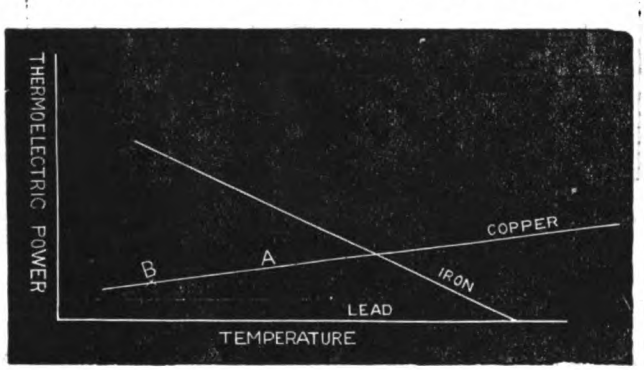

Fig. 1

true, indeed, as Prof. Stroud says, that a current flowing from hot to cold portions of a copper conductor would tend to reduce the differences of temperature. But so also would a current flowing in the opposite direction—from cold to hot. In the first case, however, the tendency to equalisation of temperature is caused only by the warming of the cold portion of the conductor; in the second case it results only from the cooling of the hot portion. In other words, when a current passes from a hot to a cold portion heat is *generated*, and when a current passes from a cold to a hot portion heat is *absorbed*. And this enables us to say at once that the direction of the Thomson E.M.F. in such a conductor must be from cold to hot, and not from hot to cold, as Prof. Stroud makes it.

Similarly, in the case of iron, in which a current tends to exaggerate differences of temperature, the direction of the E.M.F. corresponding to the Thomson effect is from hot to cold.

If this is correct—and it seems to me perfectly clear—it is certain that Prof. Stroud's experiments are not to be explained by the Thomson effect. For the currents which he observed were in both cases in the wrong direction. Nevertheless, his results are of great interest, especially those plotted in Fig. 3 of his Paper, and it is to be hoped that he will continue to prosecute his researches until the true nature of this mysterious phenomenon is revealed.

It may be as well to place on record here some further results obtained in my unsuccessful endeavour to connect the thermo-electric forces in question with a temporary or permanent change in the physical constitution of the metals, possibly due to heat. Three series of experiments were made. In the first the ordinary thermo-currents between temporarily stretched wires and unstretched wires of the same metals respectively were observed; in the second, those between hammered and unhammered wires; and in the third, those between annealed and unannealed wires. The direction of these thermo-currents is indicated in the last three columns of the table. Though the experiments failed in their immediate object, the results are not without some points of interest.

THE BIRMINGHAM EXHIBITION.

Ernest Scott and Co.—The chief exhibits of an electrical character shown by Messrs. E. Scott and Co., of Newcastle,

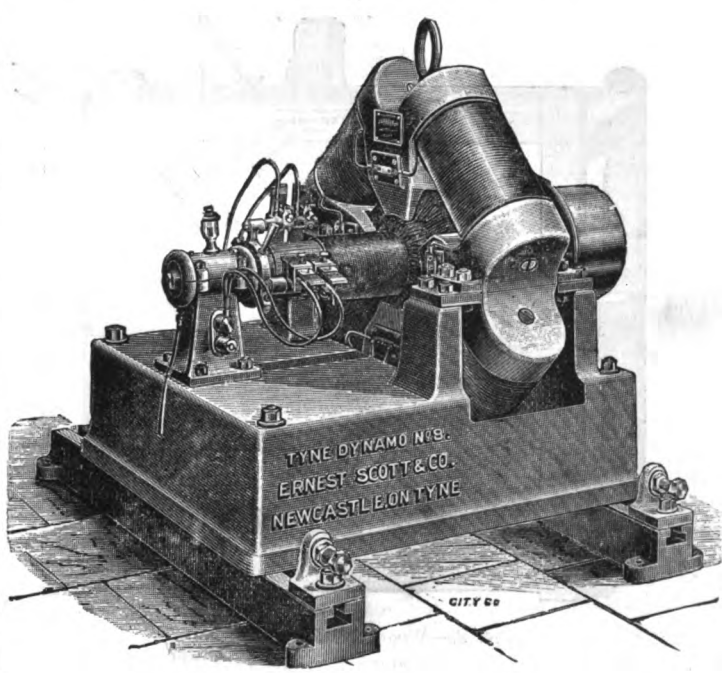

Fig. 2.—15-Unit "Tyne" Dynamo.

are a "Tyne" dynamo, a "Tyne" arc lamp, and a "magnetic separator." The "Tyne" dynamo (Fig. 1), is erected among the other machines and supplies six of their arc lamps in the main building. It is a 4-pole shunt machine. The field magnets, the form of which will be seen in the figure, consist of four soft iron cores bolted to the pole-pieces, which, are of cast iron; the two upper field magnet pole-pieces are each in one piece; the side poles, however, are in two pieces, so as to allow of the upper half being lifted without removing the lower parts. The armature is of the flattened ring type, and is wound with a single layer of wire of square section. In the 15-unit 65-volt machine exhibited there are 60 sections of four turns each, the wire being ·16 × ·14 section. To avoid the use of four brushes cross-connections are made. The spindle is of steel, with thrust collar to take up end play; the bearings are of cast iron, with adjustable keeps, and lined with brass shells, fitted with white metal. This construction has been adopted in preference to the ordinary method of running white metal into cast shells, and enables new brasses to be fitted in at a moment's notice, it not being necessary to heat the bearing to melt out the metal. The white metal itself is

Digitized by Google

of special quality, made by Messrs. Ernest Scott and Co. for their marine and other high-speed engines, and is found to have double the wearing qualities of any other metal in the market. The commutator is of drawn copper, insulated by mica, and mounted upon a gun-metal sleeve, secured to the spindle by lock nuts and a feather. Owing to the powerful magnetic field of these dynamos and the small resistance of the armature the shunt machines are practically self-regulating. The "Tyne" arc lamp is used for lighting the bays, and, as well as the "Tyne" dynamo, has been designed by Mr. Mountain. The upper carbon rod is cut in the form of a rack, and gears into a pinion, carried on a spindle running in a sliding block in the inner frame of the lamp. This block is free to move vertically, and on the outside are two brake-wheels. Upon the brake-wheels there is a rocking lever carrying two friction chains. One end of the lever carries the iron core of the solenoid, and the other end the air dash-pot. When the current passes through the lamp the core is sucked up, tightening the friction chains upon the pulleys and raising the sliding block, and thus striking the arc. When the lamp is in its feeding position the sliding block rests on two adjustable stops, and as the current weakens in the solenoid the core is slightly lowered, releasing the friction chains and allowing the carbon rod to descend. These lamps are run in parallel, with resistances in series, as usual.

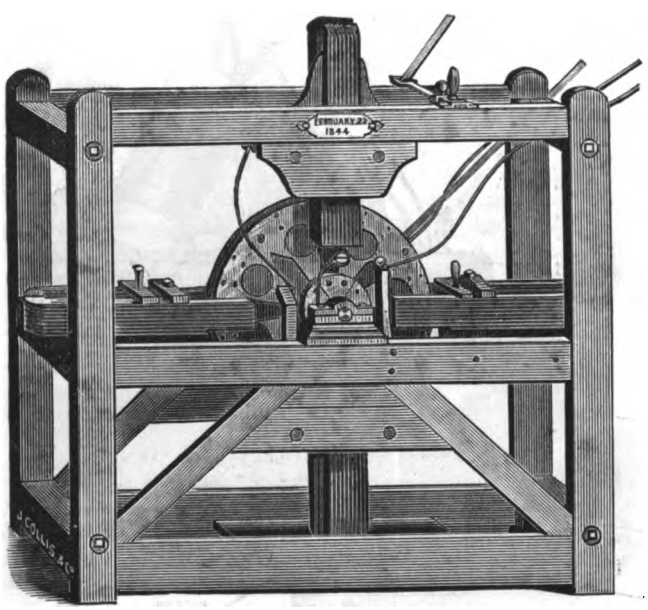

Fig. 2.—Woolrich's Plating Machine.

On their stand the company show a model of their "Magnetic Separator," which has been manufactured and used by them for the last two years. It consists of a strong frame-work on which are mounted two continuous bands passing over rollers, and moving parallel to one another in the same direction. The mixed iron and brass cuttings are thrown into a large hopper, at one corner of the machine, through which they are sifted on to one of the bands; they are then carried along under a large disc fitted with a number of electro-magnets with their poles downwards, which pick up the iron particles off the band, leaving the brass to travel onwards and fall into a box or sack at the end. The iron particles are carried round on the disc half a revolution and deposited on the other band, the magnetising current being at that moment automatically cut off.

Woolrich's Magneto-Plating Machine.—This machine has attracted considerable notice by reason of its venerable and somewhat uncouth appearance. A card attached to it states that it was invented by John Stephen Woolrich, of Birmingham, in 1842, and constructed by Messrs. Thomas Prime and Son in 1844. It has lately been presented to the City of Birmingham by the makers, and is exhibited by permission of the Mayor and Corporation. It is said to be the first plating machine ever constructed, and was used by Messrs. Prime and Sons in their business as electro-platers for many years. On the occasion of a British Association meeting Faraday visited Messrs. Prime and Sons' works to see this machine at work, and expressed great delight in seeing his discovery of electro-magnetic induction so early put to this practical use.

The general appearance of the machine is represented ie Fig. 2. The wooden frame carries four compound horse-shon magnets mounted with all their like poles on the same side, the poles all being directed towards the centre of the frame, and adjusted so that the armature can revolve between each pair. The armature coils, eight in number, are mounted between two brass discs about $\frac{1}{4}$in. thick and 2ft. in diameter. One set of ends are connected together and to a brass collecting ring on one side of the armature, whilst the other set of ends are joined to the insulated sections of a commutator on the far side.

Before reaching the commutator, however, the wires from the alternate coils are connected together by means of two independent copper rings to which they are soldered; thus the current from the four coils which are approaching or leaving the magnet poles at the same time can be collected from one commutator segment only. There are two brush-holders, however, and herein lies one peculiarity of the machine: one brush collects all the currents due to the sets of coils approaching the magnet poles, the other all those due to the coils leaving them, an independent connection being made with each brush so that two depositing baths could be worked at the same time.

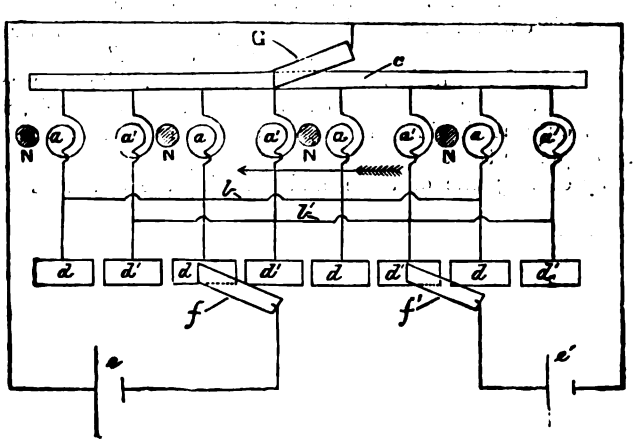

Fig. 3.

Diagram of the Connections of Woolrich's Plating Machine.

The diagram (Fig. 3) will make the action of the machine clear. For simplicity the arrangements are represented spread out flat. The magnet poles marked N (the S poles are not shown; they would, of course, be facing the N poles) are stationary, while the coils marked a and a', with their connections, are supposed to move in the direction indicated by the arrow. A current will be induced in the coils marked a as they approach the magnets, which will flow by way of the connections b and a commutator section d to the brush f, and thence to the plating bath e and back to the coils by way of the brush G. When the coils reach the centre of the poles, the brush f will be just leaving the commutator section d connecting with the coils a, while another commutator section connecting with the same set of coils will come under the brush f', and thus the reverse current as the coils leave the magnetic poles will pass through the bath e'; at the same time the coils marked a' will be approaching the magnets, and a corresponding section d' of the commutator will come under the brush f', and the same cycle of actions now takes place with the position of the two sets of coils with regard to the brushes reversed. Here, then, we have an armature with equi-potential coils connected together, so as to reduce the number of brushes required to a minimum. Truly there is nothing new under the sun!

ON A NEW FORM OF CURRENT WEIGHER.*

BY PROF. JAMES BLYTH, M.A.

In the construction of balances for the measurement of electric currents a greater or less difficulty has always been experienced in leading the current into the movable parts of the instrument without seriously interfering with its sensibility. Several methods have been adopted to overcome this difficulty. In some balances the current is led in by mercury cups; in others flexible leads, made of thin wire spirals or thin metal strips, are employed, while in the recent balances by Sir William Thomson the difficulty has been overcome by means of his well-known ligature suspension.

Some time ago it occurred to me that still another form of balance might be employed for this purpose, and the present Paper is a short description of one which I have made.

The balance referred to is of the ordinary Roberval type, with the pivot connections all replaced by tightly-stretched torsion wires. It is constructed as follows:—

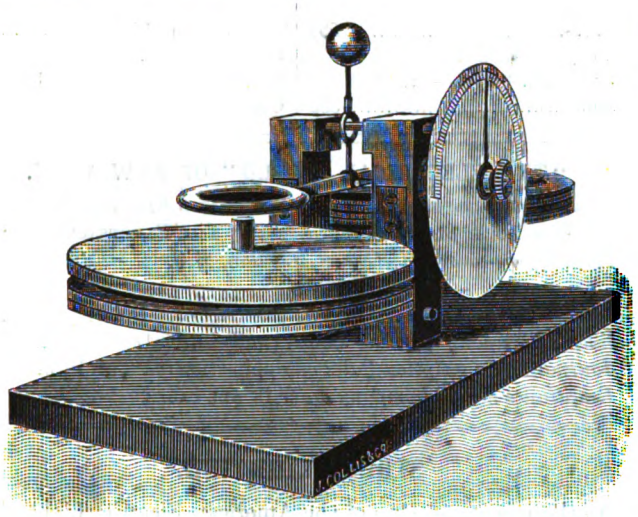

FIG. 1.

On a flat base-board (Fig. 1) are placed two vertical uprights of wood or other insulating material, about six inches apart. Between these are stretched two parallel wires in the same vertical plane about three inches apart. To the middle points of these wires are soldered the two horizontal metal bars of the Roberval. These are about nine inches long. Both horizontal bars terminate at each end either in forks or rings, placed in a horizontal plane, and wires are tightly stretched between the prongs of the forks or across a diameter of the rings. To the middle points of these last wires are attached, also by soldering, the vertical bars of the balance, thus completing what takes the place of the ordinary jointed parallelogram of the Roberval.

The vertical bars have metal terminals, insulated from each other, and carry the circular discs, on the rims of which the movable coils of wire are wound. The bars pass at right angles through the centres of the discs, and are fixed to them at their middle points. The fixed coils, which are of exactly the same diameter as the movable ones, are supported from the base-board, and are placed so that one is about half an inch above one movable coil, while the other is as much below the other movable coil. From this it will be seen that when the balance is in equilibrium the fixed and movable coils are all horizontal, with a space of about half an inch between each pair.

The stretched wires may be either of steel or phosphor-bronze, and before being finally soldered are placed under considerable tension.

The current flows through the instrument thus:—Entering, say, by the upper wire connecting the fixed supports, it passes to the upper horizontal bar. There it splits into two, one half (supposing the resistances equal) passing to each end of the bar, and, by means of the corresponding fork-wires, passing through the movable coils. From the movable coils each half returns along the lower horizontal bar and together pass out by the lower wire connecting the two main supports. From this the whole current passes first through the one fixed coil and then through the other, and in such a direction as to produce a repulsion between each pair of coils.

In the constructing care is taken that the suspended coils are both made of equal weight, and that when the balance is in equilibrium no torsion is in any of the wires. Small scale-pans are attached to each vertical bar, and a bob for raising or lowering the centre of gravity of the whole is placed on a rod springing at right angles from the middle of one of the horizontal bars.

The current strength is estimated by the weight needed to restore the balance to equilibrium when disturbed by the passage of the current. A sliding weight may also be used, as in a steelyard.

It will be readily seen that, as in all forms of current-weigher, the weights are proportional to the square of the current strength.

Another form of the instrument, which is in reality a torsion balance, is represented in Fig. 2. It differs from the previous form in this, that all the coils are in a vertical plane, with the torsion wires also vertical, while the current is measured by the

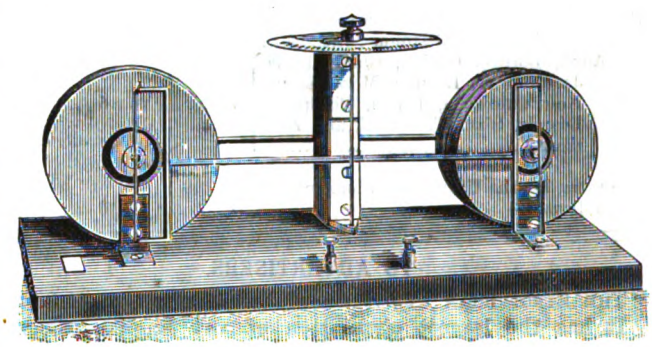

FIG 2

number of degrees of torsion that must be given to the one end of one of the torsion wires in order to bring the balance to equilibrium. If the connections be considered, it will be seen that no current passes through the wire where torsion rigidity is used to measure it, and also that the current is so distributed among the other wires that only one-fourth of the heating effect is produced on each of them which would be produced if the entire current went through them. In this way any inaccuracy due to the heating of the wires is reduced to a minimum. The balance exhibited, though little more than a model, had a resistance of 360 ohms, and is quite sensitive to one-tenth of an ampere.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

STREET LIGHTING.

At the recent meeting of the American Electric Light Association, it was stated by Mr. WEEKS, in his Presidential address, that the number of arc lights now in service in the United States is 237,017, being an increase of over 17,000 on the past six months. No distinction is drawn between the lamps employed in street lighting and those used for private purposes, but we believe the number is supposed to be about equally divided. The total number of incandescents in use is given as 2,704,768, showing an increase in the same period of a little over 200,000 lamps. (Although it does not directly concern the subject we have in hand, we may add, upon the same authority, that there are now 109 street tramways operated by electricity in the States, which employ 936 motor cars.) Returning to the lighting business, we note that, roughly speaking, it may be said that the total horse-power employed in the service is about equally divided between arc and incandescent lighting, and therefore, if our previous assumption is anywhere near the mark, about one-fourth of the central station output in the States is devoted to street-lighting. In this country, although, unfortunately, we have no authoritative statistics to go upon, yet there is not the least doubt that the ratio, so far from being equal, is more like 20 to 1 in favour of the incandescents—we refer as before to the total horse-power employed—whilst the existing street lighting probably accounts for scarcely 5 per cent. of the total number of arcs in use. In the States there are a great number of flourishing stations still wholly devoted to arc lighting, whilst with many others the incandescent work is quite subsidiary. Stations of this kind are not, indeed, wholly unrepresented in this country, and such as do exist have, as a rule, attained a very fair measure of success. The fact is, as every electrician knows, that

Digitized by Google

in an arc-lighting installation designed chiefly for street lighting, both the technical and economical problems can be solved with far greater ease and certainty than is the case with a house-to-house distribution of incandescents. Both capital-outlay and working expenses can be estimated to far greater nicety, and the exact hours of lighting are usually known beforehand, so that the preparation of estimates presents little or no difficulty. Add to this that as a rule the load is always fully on or fully off and that the working hours are from three to four times as long as the average for incandescents, and it is sufficiently clear that *if only a fair price can be obtained* street lighting ought to afford a valuable source of revenue to the electric lighting companies which are everywhere springing up. The public mind is at the present time somewhat excited about electrical affairs, and it is allowing itself to indulge in visions of outdoor brilliancy which the local authorities have in very few cases as yet taken any steps to realise. The result will probably be that as soon as some of the big stations get into operation there will be an outcry on the part of the public for better street illumination, which the local authorities will be unable to resist. Electric lighting companies will then have a chance, which we hope they will have the wisdom not to throw away.

It is, however, much to be desired, both for the sake of the public and for the sake of the Companies, that where the work is put up to public tender, the number and disposition of the lamps should be explicitly stated in the specification. Experience has shown that if two or more Companies in competition be allowed to use their own individual judgment in this matter, the result is almost certain to be unsatisfactory. The public want the electric light because they wish to see the streets better lit, and this cannot be done by merely increasing the brilliancy of the lamps, if their number be more than proportionately diminished. It is sufficiently evident that if the question is left open the company must always be tempted to underestimate the amount of light required—not perhaps without an inward expectation of later extensions when the results are made manifest. Meanwhile the public are disappointed and dissatisfied, and the light is either pronounced a failure, or additional funds are grudgingly voted. This has happened already at least half-a-dozen times in this country, and is happening at this very moment in a town which we, for the present, forbear to name.

For this reason we are strongly of opinion that, equally out of regard for the public and in justice to the Companies themselves, they should not be asked to tender to any street lighting specification in which the number and distribution of the lamps is not definitely set forth. The question is one not wholly devoid of difficulty, but it ought not to be beyond the compass of the local surveyor or the borough engineer, or whoever the functionary in charge of the existing street lighting may chance to be. The mistake which should above all others be avoided is that of having the lamps so few and far between that passengers find themselves now in dazzling light and then in s mi-darkness. The greater the intrinsic brilliancy of the lamps the more pronounced is the evil. The remedy is obviously to have a sufficient number of lamps, to place them at a sufficient hei ht, and to take into consideration the width of the thoroughfare, the nature of the traffic, and anything else which can effect the resultant character of the illumination, before finally deciding the question. Doubtless some skill and knowledge is required for this, and with greater experience better results will be obtained, often for less money. Meanwhile, the responsible officers may learn much by visiting some of the towns where arc lighting already exists, and making a few intelligent observations as to the results obtained and the arrangements adopted. From the nature of the case it is clearly impossible to lay down many general rules, but the following illustration may possibly be of some service to the class for whom it is intended:—Take the case of a quite straight thoroughfare, one mile in length, and 60 feet in width. Such a street could not be efficiently illuminated with less than 30 to 35 arcs of 2,000 c.p. (nominal) mounted upon poles from 24 to 30 feet in height, and placed, of course, on alternate sides of the road; if furnished with the dioptic lantern or some other suitable means for economically distributing the light so much the better. In cases where the introduction of electric lighting necessarily means the total abandonment of gas for the public service, the difficulty may be economically met, as in Taunton, by lighting lanes and alleys with oil lamps.

But whether, after all, arc lighting affords the best and final solution of the street-lighting problem is a point quite open to consideration. In the States not a few towns have abandoned arc lighting in their streets in favour of incandescents. In this country repeated efforts have been made to introduce incandescents for the public service, and we cannot point to one instance in which a satisfactory result has been attained. As we have repeatedly pointed out, those attempts were from the first foredoomed to failure, because in the expectation of the public "electric light" necessarily means a glare. The time will probably come when they will have been educated beyond this point, and will agree with us in thinking that about 500 candles in an incandescent, or 300 to 400 in an arc, is as much light as needs to be concentrated in a single lamp for the lighting of ordinary streets. However, we are not yet quite ready to supply such lamps—not at least at current rates—so perhaps it is as well that the demand is not over-pressing.

PARIS EXHIBITION AWARDS.

The following is a complete list of the awards of the International Juries to the electrical exhibitors of the British Section of the Paris Universal Exhibition:—

GRAND PRIZE.

Elliott Brothers.

GOLD MEDAL.

Crompton and Co.	John Fowler and Co.
Eastern Telegraph Co.	Latimer Clark, Muirhead and C

SILVER MEDAL.

Electrical Power Storage Co.	Henley's Telegraph Works Co.
Paterson and Cooper.	Sunbeam Lamp Company.

BRONZE MEDAL.

Automatic Electrical Corporation.	Chubb and Sons Lock and Safe Company.
Davis and Timmins.	

HONOURABLE MENTION.

Acme Electric Works.	Globe Electrical Engineering Co.

In addition to the above awards in Class 62 the following well-known firms have obtained awards:—Messrs. Aveling and Porter, who exhibited amongst other things a combined traction engine and dynamo, a gold medal; Messrs. W. and T. Avery, of Birmingham, who exhibited one of Snelgrove's electric balances, a silver and a bronze medal; R. Aylmer, a bronze medal; the Blackman Ventilating Company, a bronze medal; Crossley Brothers, a gold medal; Messrs. Davey, Paxman and and Co., two gold medals and one silver medal; Samuel Elliott, a silver medal; W. and J. Galloway and Sons, a grand prize; Messrs. Greenwood and Batley, a gold medal; J. Kirkaldy (Limited), a silver medal; Messrs. David Moseley and Sons, honourable mention; the North British Rubber Company, one gold and one silver medal; Messrs. Selig Sonnenthal and Co., a silver medal and an honourable mention; A. I. Timmis, a silver medal.

PURIFICATION OF SEWAGE AND CONTAMINATED WATER BY ELECTROLYSIS.*

BY WILLIAM WERSTER, F.C.S.

When some months back your Committee did me the honour of asking me to read a Paper on the Electrical Treatment of Sewage, I accepted the privilege with many misgivings, as, unfortunately, my time is so much occupied in the routine of business that I felt it would be impossible to prepare a Paper worthy the attention of this assembly. Having accepted the responsibility, I have done my best to put the subject before you clearly, and must crave your indulgence for any shortcomings.

The increasing populations of our large towns has made the question of sewage purification a very pressing one, particularly in relation to the purity of our rivers, most of which unquestionably are in a serious state of pollution. The sewage question generally has become of such importance in reference to public health, now and hereafter, that it is evident steps must be taken as quickly as possible to remedy the present condition of things, and to maintain as high a standard of purification as is compatible with the enormous quantities with which we have to deal.

It may be that the present scientific knowledge is not sufficient to entirely and finally deal with this question. We should, however, aim at as high a standard of purification as possible—it is of no use to try half measures—and whatever the treatment may be, my contention is that the nearer Nature's action is approached, the nearer the solution of the difficulty. Any new process requires thorough investigation, and it is for this reason that my experiments have taken up so much time, the success of certain laboratory experiments having been made public quite eight months before I was able to start a series on anything like a working scale, and since that time my connection with other undertakings has rendered it very difficult for me to concentrate attention except for short periods at intervals.

The oxidation of organic matter can only be attained by one mode—chemical action—whether it be by filtration, the addition of chemicals, or by mechanical force represented by the electric current.

Sewage is a most complex compound, whose component parts depend upon the water supply of a town, in some cases upon the rainfall and the industries of the locality. Householders and owners of factories would much assist local authorities in the end aimed at if they would disinfect their refuse before it passes into the sewers; thus one of the most objectionable features I have noticed in London sewage is the large amount of organic matter floating on the surface with an obnoxious odour. I am not quite certain of its source, but it is evidently of a nature that points to gas works or tar distilleries, also certain dyes and tan refuse which require more treatment than sewage itself. I know that the manufacturer is at a loss where to put his waste products, and it is an extremely difficult question for the public to solve; but it is a moral certainty that, if the sanitary authorities of our cities and towns have to purify their sewage, the taxpayer will decline to pay for the treatment of manufacturers' refuse when it is known that sewage alone requires very much less expenditure on purification than when it is mixed with complicated waste compounds of a chemical nature. The great object in view is to prevent putrefaction, and it may not be out of place to state the means of arresting it.

The question is, what is putrefaction? Putrefaction is a spontaneous change common to all organic bodies when exposed to the air; the action is accompanied by the evolution of unpleasant gases, which are, for the most part, compounds of sulphur and phosphorus; it differs from decay, as it is not oxidation; the presence of air is essential only at the commencement of the action, and not after it has fairly set in. Modern science teaches us that air may be the carrier of ova which induce the change. Any dry matter does not putrefy; intense cold prevents putrefaction.

The atmosphere acts mechanically by its power of removing foul vapours, and chemically by their oxidation.

* Paper read before the British Association in Section G. Newcastle-on-Tyne, September, 1889.

Water—its action is largely mechanical. Thus in a river organic matter becomes separated, and oxidation takes place by reason of the air dissolved in it; showers of rain purify the air, and the molecules of water forming the rain act as carriers of oxygen.

The soil, as manifested in our graveyards, the iron oxides in the soil acting as purveyors of oxygen, and owing to its porosity causes the oxidation of putrefying matter. Intense heat and light also play important parts in disinfection.

Sewage farms can only be successful when the porosity of the soil is adapted for filtration, and when the area is sufficiently large for the work it has to do; but all sewage before being run upon the land should be treated so that secondary putrefaction cannot be set up.

The organic matter should also be disintegrated, so that the pores of the natural filter shall not be blocked up by it when in a state of semi-solution. Greasy matters should be removed, as they also have a tendency to block up the soil.

Before entering into the particular subject of my Paper, I must ask you to glance at the list of a few of the chemical processes which have been tried in various parts of the world during the last 120 years.

Name of Substances.	Inventor.	
Sulphate of iron	Deboissieu	1762
Chlorine	Halle	1785
Lime	Estienne	1802
Powdered charcoal	Giraud	1805
Chlorine and chloride of lime	Guyton Morveau	1805
Ashes	Chaumette	1815
Sand	Duprat	1818
Sulphate of iron	Briant	1824
Chloride of soda	Labarraque	1824
Waste chloride of manganese	Payen and Chevalier	1825
Sulphate of lime	Siret	1827
Animal charcoal	Frigerio	1829
Peat	Guibourt and Sanson	1833
Charcoal and calcined marl, or river mud	Pottevin	1836
Sulphates of iron and zinc with tan and tar	Siret	1837
Earth, lime and waste substances	Rossier	1837
Peat ashes	D'Arcet	1840
Metallic oxides and carbon	Krafft and Suequet	1840
Chloride of zinc	Sir William Burnett	1840
Schist coke	Hompesch	1841
Trade refuse, charcoal and ashes	Albert	1842
Powdered lignite	Jourdan	1843
Impure alum	Siret	1843
Sulphate of zinc, charcoal and clay	Gagnage and Regnault	1844
Persulphate of iron	Baronnet	1845
Schist coke	Du Boisson	1845
Chlorides of iron and zinc	Dubois	1846
Lime and precipitating tanks	Higgs	1846
Nitrate of lead	Ledoyen	1847
Waste salts of iron, lead, zinc, &c., with pyrolig matters, ashes, &c.	Brown	1847
Pyrolignate and perchloride of iron	Ellerman	1847
Impure chloride of manganese	Young	1847
Dried seaweed, lime, and sulphate of lime and zinc	Salman	1848
Peat charcoal	Rogers	1848
Charcoal, soot, mineral salts, &c.	Legras	1849
Spent tan, carbonised	Tarling	1850
Fresh bark, sulphate of iron, and peat charcoal	Angely	1850
Metallic sub-salts, as of iron, alumina, &c.	Browne	1850
Milk of lime and collecting the deposit	Wicksteed	1851
Acids and metallic salts, and filtrations through charcoal, clay, peat, gypsum, &c.	Dover	1851
Lime, sulphates of alumina, and zinc and charcoal	Stothert	1852
Lime, magnesian earth, sulphate of zinc or iron, and vegetable charcoal	Gilbee	1852
Sifted ashes, breeze, or peat charcoal	Perks	1852
Sulphate of zinc, potash, alum and sand with waste tan, ashes, lime, soot, &c.	Pinel	1853
Metallic sulphates, metallic chlorides, or charcoal and magnesian salts	Herapath	1853
Salts produced in working galvanic batteries	Dering	1853
Peat or bog earth containing salts or oxides of iron	Dimsdale	1853
Peat and other charcoal and chloride of sodium, &c.	Macpherson	1853
Animal charcoal, alum, carbonate of soda, and gypsum	Manning	1853

Name of Substances.	Inventor.	
Soft sludge from alum works, with lime and charcoal	Manning	1854
Peat charcoal carbonised with oil of vitriol	Longmaid	1855
Alum schist or shale, and other aluminous minerals, with lime and charcoal	Manning	1855
Manganates and permanganates	Condy	1857
Superphosphate of lime with magnesia and lime	Blyth	1858
Sulphate of iron with lime in solution (recommended only), &c., &c.	Letheby	1858
Spongy iron	Bischoff	1865
Iron finely divided in revolving cylinders	Anderson	1884
Iron sulphate Aluminium sulphate Calcium sulphate Magnesium sulphate Silica Black oxide of iron	Named Ferrozone	1887

It is I fear true that many of the methods enumerated, and most of those not enumerated, have not only failed to meet reasonable expectations as to their physical and sanitary characters, but they have also proved in many cases costly failures; and it is a remarkable fact that claims have been made within the last five years in reference to sulphate of iron by itself, or in combination with other materials, as if it had only just occurred to the chemical mind that these substances ought to be tried. On reference to this list, you will notice that the first five, dating from 1762—1805, are practically identical with those of recent date. In 1843 alum seems to have been tried, and in 1857 manganates and permanganates; the latest development of sulphate of iron is under the name of ferrozone. It was while working with perchloride of iron as a purifier of sewage that I first learned the importance of iron salts in relation to organic matter, and it was in connection with this chemical and free chlorine gas that the idea of electrolysis suggested a possible mode of treatment of water contaminated with organic matter. Sulphate of iron has one great drawback—the production of sulphide of iron due to the organic matter combining with the oxygen of the salt. In nature we have iron pyrites, known as the bisulphide of iron, which is produced by the deoxidation of sulphate by organic matter. The sulphuretted hydrogen in sewage is entirely due to the same action on the sulphates contained in it; it therefore follows that sulphates should not be added, as they only increase the nuisance instead of abating it. Sulphuric acid added to manganate of soda and run immediately into the sewage is sure to lead to objectionable reactions. The very fact of adding chemicals means adding water, thus, to a certain extent, producing a seeming purification. The following illustration will show this:—

Ten grains of lime added to a gallon of sewage in the form of lime water means the addition of one pint of water; it therefore makes an apparent purification of 12·5 per cent. by this increase of water. I have here a list of analyses taken from the Appendices of the Report of the Royal Commission on Pollution of Rivers; my experience being that lime produces after-putrefaction if used alone or with sulphates, and if used in large quantities is also sure to set up after-precipitation when the resulting effluent is run into river water.

I have already stated that putrefaction means sulphuretted hydrogen. On the West Coast of Africa the water contains large quantities of sulphuretted hydrogen, its formation being due to the presence of organic matter and sulphates. I believe I am right in saying that this particular portion of the African Coast is known as the Sailors' Death-trap.

Of artificial disinfectants chromic acid is the strongest, sulphurous acid the weakest among mineral acids. Permanganates oxidise dead organic matter under certain conditions, but unless in very concentrated solutions, have little or no action on disease germs. Chlorine gas or oxides of chlorine are the most powerful disinfectants.

The fact that water is easily decomposed, provided the current electricity is of sufficient intensity, and also that the effects produced are precisely in accordance with the chemical equivalents of the substances electrolysed, is practically the explanation of the whole system; for the chemical changes that take place in sewage when it is electrolysed depend chiefly on the well-known action that sodium, magnesium, and other chlorides (which are always present in sewage) are split up into their constituent parts. Thus we have at the positive pole chlorine and oxygen set free, and these elements are liberated in a nascent state, a condition in which they are intensely active, so that the organic matter in the sewage is rapidly oxidised into innocuous compounds. So rapid is this action that, provided the sewage contains a sufficiency of chlorides, it is possible to produce a disinfecting fluid from it consisting of oxides of chlorine.

As mine is an artificial action, I will take the two disinfectants which are formed in my process, iron oxides and chlorine: the first a purveyor of oxygen; the second, in the form of hypochlorites or chloric acid, absolutely destroys organic matter, living or dead. By using non-oxidisable plates, such as carbon for positive pole and iron at the negative pole, with a porous diaphragm between them, I am able to collect the component parts of the mineral salts; therefore at the non-oxidisable plate I obtain a solution of chlorine and oxide of chlorine, and at the negative plate I obtain ammonia, soda, and potass, which in their turn precipitate any lime and magnesium salts that may be present in the liquid. So strong is the action of oxide of chlorine that it is only one form of carbon plate that will resist disintegration.

My first experiments carried out in this manner were conducted with platinum plates, but the experience was that the cost of platinum put it out of the question, besides which there was a very slight action on the positive plate which distinctly pointed to its ultimate destruction. There being no precipitation in the sewage of matter in suspension, by means of an arrangement, which consists of a porous pot with a non-oxidisable plate such as carbon for the positive electrode and iron plates for the negative electrodes, I am able to manufacture the before-mentioned solution of oxides of chlorine from brackish sea-water or sewage. The water of the River Thames near Barking is admirably suited for this purpose. It is possible that an objection may be raised that the resistance of the porous pot to the electric current would be so great that the cost would render it an impossibility from a commercial point of view, but the very fact of using salt water balances the extra resistance caused by the porous diaphragm, and for every ampere of current that is used per hour I produce 18 grains of nascent chlorine, or an equivalent of the oxides of chlorine. My experience of nascent chlorine as a disinfectant is that about one-third of a grain is capable of disinfecting one gallon of London sewage (first removing the matters in suspension), and on examination the presence of nitrites is detected, which shows how far the oxidation has been carried. This action, combined with the treatment with iron plates, hereafter described, will, if carried far enough, absolutely eradicate all organic matter. And here it will be as well to mention that the resulting effluent must not have an acid reaction, otherwise fungoid growths appear on the surface after a few hours. The forms in which these apparatus are best applied on a small scale, with porous diaphragms, are as follows:—First. An outer vessel, which may be made of iron—the sides in that case acting as negative electrodes—and an inner vessel containing the carbon electrode. By means of a syphon connected with a reservoir or tank, containing, say, sea water or salt and water, the inner vessel can always be kept supplied with the saline solution, and by an easy automatic arrangement it is possible to draw off a given quantity of disinfectant solution when formed. By placing an oxidisable plate in the same pot as the carbon, and connecting the two to the positive pole of the current, I can produce a hypochlorite or chloride of the metal used, which will thus further assist the resulting action. The many uses to which these disinfectants can be applied I need not enlarge upon. Six small cells of the latest form of the Leclanché type are quite sufficient for producing the necessary power for making two or three gallons of the chlorite solution during the day, and they will last for several months without recharging, it being understood, of course, that they do not remain continuously in action. The apparatus on a large scale may be variously modified according to the strength of the solutions of chlorides acted upon.

By applying the current to a carbon filter as arranged (Fig. 1) I am able to oxidise the organic matter in water. The positive pole being the porous carbon block, the nascent

Digitized by Google

oxygen produced in the pores of the carbon by the electric current absolutely destroys the organic matter, bacteria being killed and the filter block itself kept clean. The action of porous carbon by itself is due to its power of absorbing noxious gases and effecting their destruction by bringing them into contact with atmospheric oxygen, but it is absolutely essential that there should be a free supply of air; how much more active the action is when nascent oxygen, and even chlorine, are constantly supplied to the pores of the carbon by means of the electric current can be easily imagined. As an example, the following analysis before and after action may be of interest :—

FILTER EXPERIMENT ANALYSES.

Parts per Gallon.

—	Appearance.	Odour.	Oxygen required to oxidise the organic matter.
Before action—Dilute sewage	Turbid	Bad	0·93
After action—Nitrites present	Clear	None	·17
Before action—Contaminated water.	Slightly turbid	Slight	·06
After action—Contaminated water ..	Clear	None	·00
Before action—Dilute sewage	Turbid	Bad	0·82
After action—Ordinary carbon filter	Slightly turbid	Slight	0·4
After action—Electric filter	Clear	None	0·13

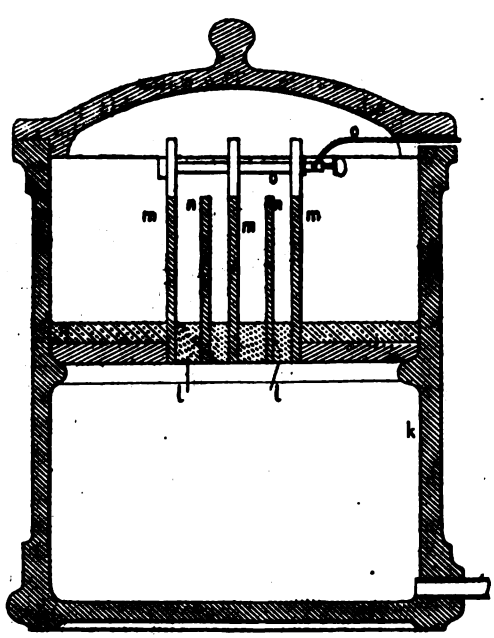

FIG. 1.—Filter for Household Purposes.

k, stoneware vessel; *l*, porous filtering material; *m m*, carbon electrodes connected by conductors *o* to the + pole of the battery; *n n*, carbon electrodes connected to − pole.

For the purposes of this filter, an ordinary form of stoneware, divided so that the lower compartment contains rather more than the upper, is used; a carbon block is fixed in the usual position, and round this block two pieces of asbestos twine are tied; at the top of the block a platinised screw terminal is fixed; this forms the positive electrode. For the negative electrode, carbon rods are arranged so that they press on the asbestos twine; they are all connected together by means of a carbon disc at the top, also provided with a screw terminal, or, instead of the rods, a carbon cylinder may be used. All that is required is to attach these terminals to the respective terminal of a battery, consisting of three Leclanché cells, arranged in series. The action is automatic, as when the top compartment is full the battery is in action, when empty it is at rest.

On a large scale I have the filter arranged somewhat in the form shown in Fig. 2. Alternate layers of small coke free from sulphur are separated either by layers of sand or perforated tiles; by suitable connection these beds of coke form positive and negative electrodes, the first layer of material being sand, so as to mechanically separate matters in suspension. It is impossible for disease germs to propagate, owing to the nascent oxygen and chlorine produced when the filter is in action.

Another form is by embedding non-oxidisable plates in sand with or without porous diaphragms. The necessary electric current in this case would, of course, be taken from a dynamo. For the treatment of sewage it is absolutely necessary that precipitation of the matters in suspension should take place, and the more complete this is the better the ultimate result.

To produce this I employ oxidisable plates of such material that they shall have no poisonous after-effects either on land or in rivers. The metals should be either aluminium or iron, but the first-named is out of the question owing to cost, and then iron, besides having the advantage as regards price, in the form of oxide has many valuable qualities, one of the chief being that sulphuretted hydrogen cannot exist when ferrous or ferric oxides are present. It is well-known that oxide of iron in the hydrated form is largely used for purifying coal gas from sulphuretted hydrogen.

The electric action is easily explained practicably (experiment shown of action of small iron plates connected with a battery, two plates being positive and two negative; sewage acted on in cylindrical glass vessel). At the positive pole the chlorine and oxygen given off combine with the iron to form a salt, which I am persuaded is, for the moment, a hypochlorite of the metal,

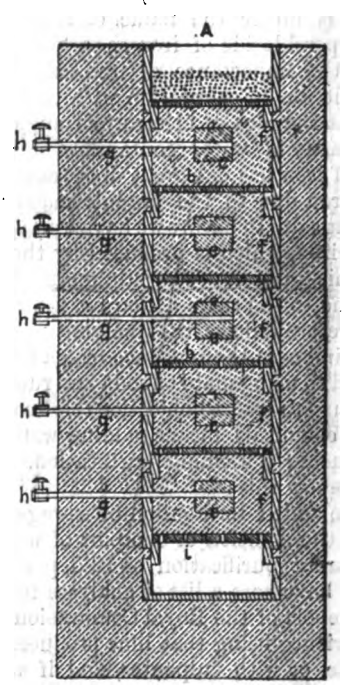

FIG. 2.—Filter arranged for operations on a large scale.

A, sand; *b*, perforated tiles; *c g h f*, carbon electrodes; *i*, channel for exit of filtered fluid.

but it immediately changes into a chloride, which in its turn is deprived of chlorine to form ferrous carbonates and oxides. During the chemical action carbonate of iron exists in solution, and its formation is due to the presence of carbonates in the sewage, chiefly carbonate of ammonia. In samples that are absolutely free from dissolved oxygen, the ferrous oxide in the white form is precipitated, and on shaking up with air it changes to the usual pale green colour; the carbonate of iron at the same time being oxidised, the ultimate precipitate is red, known as ferric oxide, Fe_2O_3, and I have noticed that sometimes this changes after a time back again to the ferrous state Fe O, thus showing that it has acted as a carrier of oxygen to the organic matter present. On a small scale the precipitate is carried to the top, due to the bubbles of hydrogen collecting round the particles of matter in suspension, but it ultimately sinks in the usual manner. In practice the precipitate does not rise, owing to the larger evaporating area, which allows the escape of the gases produced. The current required for the action varies with the

Digitized by Google

nature of the sewage; but in this case I am using an ampere of current, and the amount of sewage is one-eighth of a gallon. It is usually assumed that 1·5 volts are required for splitting up water into its component parts; this may possibly be true with carbon plates, but with iron plates acting on sewage I can obtain the same result with ·9 volts as with double the intensity; of course, it takes a longer time, for with such a low voltage the quantity of current is small.

An ordinary sample of sewage requires, on an average, one ampere of current for 10 minutes per gallon, but when mixed with foreign matter, such as manufacturers' waste products, the amount required can only be estimated by experiment. The small plates I used in the experiment are of wrought iron; on a larger scale I use cast iron of the commonest "pig" quality, which is only one-third the cost and has the virtue of not scaling. Most of my experiments have been carried out with wrought iron sheet, which has the disadvantage of scaling, but on account of its lightness is more suitable for experimental work. The plates themselves should always be kept under water, so as to prevent the formation of the red oxide on the surfaces; and the action should be continuous as far as possible, for if continuous the plates seem to acquire some property which reduces the resistance to the electric current, and therefore lessens the cost. At the beginning of a month's run which lately took place, the voltage measured across certain plates was 3, but after a few days only 1·79, and doing the same work. On examining the plates freshly taken from the liquid they were in, I found a thin coating of the black, or magnetic oxide of iron, which has the property of preventing the rusting of the plate under water when the electric current is cut off.

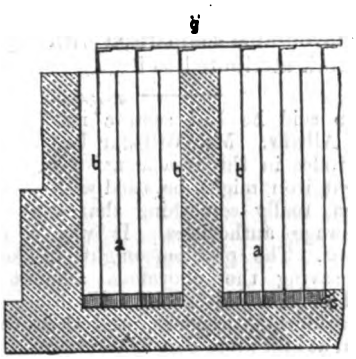

FIG. 3.—Brick Channels with Iron Electrodes in position.

a, negative; *b*, positive; *c*, asphalte; *g*, main lead.

For 1,000,000 gallons sewage flow, 24 hours, the complete plant necessary is:—engine, dynamo, and boiler-house; two engines and boilers, each 12 horse-power nominal; two dynamos, brick shoots with culverts at side, two settling tanks, sludge tank, sewage culvert, treated sewage culvert, cast-iron plates, copper conductor, measuring instruments. Where the effluent has to run into a small stream or river a suitable tank would have to be constructed for arranging the electric filter as before described.

The drawing Fig. 3, representing the plates in position, shows that a channel is kept at the bottom of the electrodes for the silt to collect, with a culvert at side to flush it into so as to prevent any block occurring, but the advantage of this is obvious. The plates in each section are about an inch thick, and can be of any length up to 6 feet; it may be possibly objected that a large number of plates is required. This may be so, but the larger the number of plates the less the engine-power required, and the longer they last. In each section the electrodes are in parallel, and any one section is in series with the other, the arrangement being exactly like that of a series of primary battery cells.

By actual experience I have been able to prove that at least 25 sections of electrodes should be in series, and across any one of these sections the potential difference need not be greater than 1·8 volts, the current being of any desired amount according to the surface of plates used. In experiments that were lately carried out I used a current of 370 amperes, which was calculated as ·23 ampere per gallon per hour; or, taking it in watts, the estimated horse-power required per million gallons in twenty-four hours was 23. The organic matter in solution of the particular sewage acted on on this occasion showed a reduction of 61 per cent. after treatment. The plates, even at half an inch apart, show no signs of blocking. The liquid to be acted on of course should be screened in the usual way and allowed to run through the plates as rapidly as the treatment required will allow, so that every molecule shall come into contact with the surfaces of metal. During a run that lately took place the measurement across the electrodes proved that 19 estimated horse-power was required to treat 1,000,000 gallons in twenty-four hours, the resulting purification of organic matter in solution amounting to an average of 50 per cent., the waste of the iron plates showing an average of two grains per gallon of sewage treated.

In putting down plates for the above quantity of sewage I should allow sufficient weight for five or ten years' consumption; what remained of this could be sold as "old iron" at the end of that time. One of the advantages of having the plates in series is that if anything goes wrong in any particular section it can easily be set right, the current being cut off during the repairs. The shoot containing the electrodes should be coated inside with some sort of asphalte, so as to prevent, as far as possible, any leakage of current to earth, the asphalte acting as a sort of insulator. The highest efficiency would be obtained by using direct driving, provided that the engine is of first-rate workmanship, and the dynamo constructed to run at a comparatively low speed. This saves in transmission, and prevents any difficulty that might arise with belting. Consumption of coal under the best conditions may be taken to range from 1·8 to 2·5lbs. per horse-power hour; the cost of fuel and iron varies so much in different districts, the prices in London being nearly double those near mining localities, that I leave the question of an accurate estimate open. Discounting this, it may be taken that the capital outlay necessary for complete plant, and capable of dealing with the sewage of a small town, amounting to a flow of 1,000,000 gallons daily, would be about £6,000 or £7,000, the engines and dynamos being in duplicate, as I presume most engineers would agree they should be. The quantity of iron plates included in the above sum would be serviceable for ten years, as far as one can foresee, and I am also assuming that the town where this plant would be erected has no appliances for treatment, such as precipitating tanks, &c.; where these are already in existence the cost would naturally be less. In reference to the cost per million gallons the same arguments hold good as to the situation of the town ruling the price. Since my first calculations were made, the rise in the markets has increased the cost of working; but it can be arrived at by the average consumption of iron, and the necessary horse-power. Thus: the daily waste of iron may be taken as 286lb., and the consumption of coal three-fifths of a ton; the labour required for working a plant of this description would be two shifts, two men to each shift.

By combining the treatment of sewage flowing between metal plates with the electric filter, it is possible to produce any degree of purity required. In this case the sewage, after action with the iron electrodes, is allowed to flow into a settling tank, and after remaining there for an hour for the precipitate to subside the effluent is passed through the filter, any oxide of iron that may be present tending to keep the top layer of filtering medium free from any objectionable action, and in turn forming a filtering medium. As the filter consumes no material, and does not require any additional engine power, for in using it the electrolytic action with metal plates not being carried so far, the cost of its working need not be considered. When a sufficient amount of oxide is deposited on the top layer of sand it can be removed, allowed to dry, and sold to gas works. The resulting sludge contains 6 per cent. of iron oxide, which does not represent the waste of the plates alone, for, in London sewage, the wear and tear of the tires of wheels, horses' shoes, &c., in the streets, means oxide of iron in its composition. One sample taken some months back contained no less than six grains iron oxide in the gallon before treatment.

Sir Henry Roscoe has kindly consented to my quoting a few extracts from his report and the analyses made by him during the investigation of this process. He states:—

"The quantity of sewage operated on in each experiment was about 20,000 gallons."

"The reduction of organic matter in solution is the crucial test of the value of a precipitating agent, for unless the organic matter is reduced, the effluent will putrefy and rapidly become offensive. I have not observed in any of the unfiltered effluents from this process which I have examined any signs of putrefaction, but, on the contrary, a tendency to oxidise."

"The absence of sulphuretted hydrogen in samples of unfiltered effluents which have been kept in stoppered bottles for three weeks is also a fact of importance."

"The settled sewage was not in this condition, as it rapidly underwent decomposition in two or three days even when in contact with air."

"By this process the soluble organic matter is reduced to a condition favourable to the further purification by natural agencies."

TABLE I.—*Sir H. Roscoe's Analyses.*

4	72·6	50·0
5	76·5	87·5
6	73·0	87·5

Another series of experiments carried out by Sir H. Roscoe, which I have tabulated (Table I.) show an average reduction of 60 per cent., although the full treatment was not carried out. I have also other lists of analyses by Dr. Meymott Tidy and Mr. Midwinter, which show equally favourable results. I have also tabulated analyses of my own, carried out in 1886, showing the electrolytic action on contaminated canal water (Table II.). Here are analyses (Table III.) of samples taken from each section of the shoot, there being six in series. The organic matter is seen to be gradually reduced by the electro-chemical action. I have never seen an effluent treated in the way described show any signs of secondary decomposition nor develope sulphuretted hydrogen.

Effluent from settling tank, taken while still flowing from the shoot	1·1

The effluent showed no signs of decomposition after a period of 14 days.

In cases where specially prepared or suitable land of a porous nature is procurable the effluent might be wholly or partially used for manuring crops, in which case the sewage should be only so far treated that the prevention of putrefaction is assured.

The advantage of iron in the soil is one which, I think, every practical man must acknowledge. I had some sludge (deposit after electric treatment) pressed without the addition of lime, and it was applied to vegetables, the result being that a marked difference in favour of iron manure was shown in the crops when compared to others grown with ordinary farm-yard manure.

The question of sludge disposal is a difficult one, and, as my Paper is essentially electrical, I will only mention that I should, where practicable, puddle it with chalk, and run on to waste lands, through wooden conduits, similar to the process of mixing clay and chalk in a washing mill, and running into backs, as carried out in cement manufacture, the only alternatives being filter-pressing or shipping out to sea.

The bacteria question is one which has probably still to be settled; but, being anxious to have some information as to the action of the iron compound produced by electro-chemical decomposition, I had some experiments carried out, with the result that after a given treatment the whole of the bacteria were killed. In the case of experiments carried out in Paris, with ordinary treatment by means of iron electrodes, the results were as follows:—

	Raw sewage.	Effluent.
Organisms per cubic centimetre.....	5,000,000	 600

Another experiment, in which the effluent was treated still further, so that a slight odour of oxide of chlorine was perceptible, destroyed all organisms, and the liquid remained sterile.

In conclusion, I submit that the application of the electric current in the several ways I have endeavoured to describe produces a precipitating and oxidising action similar to natural processes, in which the organic matter is destroyed by oxidation due to dissolved oxygen slowly absorbed from the air, assisted in many cases by matters in the soil, such as oxides of iron, acting as carriers of oxygen, and I also consider that the question of cost will bear favourable comparison with any process which really does the work attributed to it.

Mr. SHOOLBRED said he had seen a number of experiments carried on at St. Albans. Mr. Webster had alluded to the use of cast-iron electrodes in the treatment of sewage. There were cases when wrought iron might be used with advantage. In this scheme there was really something that was well worth consideration by sewage authorities. It was a most important question for towns. The problem might be looked at in the broad light of saving the enormous amount of chemicals, principally in the form of chalk and lime, which had to be bought at considerable expense, and then the sludge itself had to be removed at still more cost to the town. It was a question whether this immense amount might not be saved to a very large extent by the expenditure of a certain sum on coal for driving certain engines to produce the electric current. The experiments certainly pointed to the fact that the whole system was well worth the consideration of the authorities of those towns where admittedly the sewage question was one of daily and hourly increasing burden as well as importance.

The PRESIDENT (Mr. William Anderson) said he was extremely glad the Paper had been written, because it put in a definite manner on the highest authority a statement about which rumours had been floating for two or three years. He thought there was a hope that this process would be, at any rate, one of the solutions of the great sewage question

---

MR. BOY'S METHOD OF SUSPENSION BY QUARTZ FIBRES.—PRACTICAL HINTS.

We make the following extract from Mr. Vernon Boy's recent Cantor Lectures, which are now appearing in the *Journal* of the Society of Arts:—

The following hints may be of use to those who are going to mount apparatus upon fibres for the first time:—Having chosen a fibre of the right diameter, and longer than is ultimately required, the first thing to do is to fasten a small fragment of gummed stamp paper to one end. This acts as a weight, and makes the following processes more easy. The upper or fixed support must next be fastened to the free end of the fibre. I prefer a common blanket pin passing through a cork to any of the more elaborate contrivances in common use; however, whatever is going to be used for the fixed support should be pointed at the lower end.

If the needle or other thing to be supported is very light, *i.e.*, nowhere approaching the breaking weight of the fibre, shellac var-

Digitized by Google

nish is the best thing to use as the cement. Just moisten the last five millimetres above the pin with this varnish, and—holding the fibre near its free end in one hand, and the pin in the other, with the little finger of one hand resting against the little finger of the other, for the sake of steadiness—immediately apply the fibre to the varnished surface, to which it will stick. Then pull it endways through a distance of half a millimetre about, to make sure that when all is dry there will be no sudden bend in the fibre. A hot piece of wire, or knife, or pair of pliers must then be applied to the pin above the varnish, so that the heat may be conducted down slowly to drive off the remaining alcohol and melt the shellac. After this the fibre is securely held at that end.

If the thing to be supported is very heavy, varnish is not so good as melted shellac, but this is much more difficult to apply. The pin must be warmed and smeared near the joint, and while hot the fibre must be applied and slightly pulled. Whether varnish or melted shellac is used, it is essential to work in a proper light. A table in front of a large window in the day, or supporting one or two movable gas burners at night, will do perfectly provided that a really black background exists, upon which the fibre may be made evident. Black velvet, or paint, or paper is no use whatever. The only background that does well, and one that is easily arranged, is the darkness inside a drawer just pulled out an inch or two.

Assuming that one end of the fibre is properly fastened, the next thing is to determine the exact length required. For this purpose I always make a drawing on a perfectly clean and smooth board, showing the point of the pin at one end, the extreme end of the thing to be supported, and the position of the mirror or whatever determines the length of the fibre.

The holding-pin is then raised up until the paper weight is hanging in the air. This is then allowed to rest on the board, and slowly dragged along until the point of the pin is exactly over the corresponding mark on the board, and the paper wafer is in the line of, but beyond, the other mark. The fibre is then straight, and must pass over the mark which indicates the upper end of the apparatus that is to be suspended, though, of course, nothing can be seen. A knife is then drawn across the board, say five millimetres beyond this mark. By this means the fibre is cut, and the five millimetres are left for the purpose of attachment. The needle or suspended thing is then fastened in the same way as the pin. It is well then to drag the needle along until the mirror is exactly over its place on the drawing, and see if the upper pin is also in its place. By warming either pin, and pulling the fibre, a slight alteration can be made if necessary.

The paper weight with the remainder of the fibre may then be taken up, and the free end fastened on a microscope slide and labelled, so that the diameter of the fibre may at any time be found. If the fibre, illuminated by a distant light, had been examined with a prism first, and the dark bands of the spectrum had been found straight and uniform from one end to the other, and it is only such fibres that I use, then the diameter must be the same over the whole length.

THE THOMSON ELECTRIC WELDING PROCESS.*

BY W. C. FISH.

The art of electric welding was first brought into application by Prof. Elihu Thomson, who had the questionable misfortune of accidentally short-circuiting an induction coil, which resulted in the fusion of the copper wire of the coil. Professor Thomson first publicly exhibited this process in New York in 1887, and it is now among the growing applications of electric energy. The electric weld was generally made by the passage of a suitable current through the pieces to be welded, combined with the application of pressure forcing the pieces together. The different fluxes employed in the electric process are similar to those used in the ordinary methods of welding. By the electric welding process it is possible to unite most commercial and precious metals and alloys and several combinations of different metals and alloys. Most of these substances have hitherto been unweldable by other processes, chiefly owing to the inability to nicely regulate the supply of heat to the weld, and to the impurities existing in the forge fire and other commercial sources of heat. The process can be used in those places where a forge fire would be a source of annoyance or danger. The nicety and certainty of the work is obtained chiefly through the cleanliness of the heat employed, and also because the pieces to be welded are held in correct relative position during the entire operation.

Discussion.

Mr. ALEX. SIEMENS confirmed the general results of the paper, remarking that they had made joints for strengthening wires by electric welding when their firm took out an Atlantic cable 12 years ago.

The PRESIDENT said the process would be of enormous value if they were able to weld finished work without destruction. The welding of boilers for instance, and the welding of rivets *in situ* would be a great gain.

* Abstract of Paper read before the Iron and Steel Institute, in Paris, September, 1889.

THE ELECTRIC LIGHT AT PADDINGTON.

SPECIAL MEETING OF THE VESTRY.

The adjourned special meeting of the Paddington Vestry was resumed yesterday. The discussion was resumed on the following motion, proposed by Mr. Mark H. Judge, seconded by Mr. W. H. Mills, and carried as an amendment to Mr. Minchin's motion :—

"*That inasmuch as the Electric Lighting Committee has not seen its way to recommend the Vestry itself to undertake to provide electricity for lighting and other purposes in the Borough, it is desirable that steps be now taken to secure it being done at an early date by private enterprise under a Provisional Order approved by the Vestry as the Local Authority.*"

Mr. LEE moved the following amendment :—

"*That the whole question of electric lighting in Paddington be referred to eleven members to form a Special Committee.*"

During the last two or three years the question of public lighting by electricity had made rapid strides. Eleven companies had laid down wires over various parts of London, and three millions had been invested in the various undertakings ; it was, therefore, absurd to speak of the Vestry speculating with the ratepayers' money. He advocated the undertaking being left in the hands of the Vestry. The opinions of two experts had been obtained at a cost of £150, yet the Electric Lighting Committee had reported against their opinions without giving any reasons. He asked the Vestry to refer the matter to a Special Committee, and not tie their hands by passing Mr. Judge's resolution.

Mr. MINCHIN pressed the Vestry to do the work themselves. When he proposed last week a loan of £50,000 being raised it was not proposed to spend it all at once—£25,000 would probably suffice, and as more applications were made for the light more capital would be employed.

Mr. M. H. JUDGE then asked the Vestry to agree to his resolution. He said it was impossible to get a Provisional Order by 1890. He was of opinion that the whole of Paddington should be supplied with the electric light, but this of course was conditional. If certain districts did not apply for it, of course they would not have it.

Mr. LEE then withdrew his amendment, and Mr. Judge's resolution was put as a substantive motion, and after a little discussion was passed unanimously, as was also his further motion that it be referred to an Electric Light Committee of 11 members to prepare a draft Provisional Order by making such modifications in, and additions to, the latest Model Order issued by the Board of Trade as they deem necessary. The following 11 gentlemen now form the Committee : Colonel Barchard, Colonel Blair, R.E., Mr. W. Clarke, Mr. Jephson, Mr. Mark H. Judge, Mr. Maberly, Mr. W. H. Mills, Mr. Minchin, Mr. Williams, Mr. Stephenson, and Mr. Chapman.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 21, 1889.

The chief event of last week was the meeting of the National Telephone Association at Minneapolis, when the eleventh Convention of that body was held under very pleasant auspices. The one thing that occurred to mar the enjoyment of the occasion was the display of the determination on the part of several of the members not to have the proceedings made public. This was very much against the desire of other members, and very much to the annoyance of the electrical journalists, some of whom had spent a large sum of money and travelled 1,500 miles in order to be present and to participate. I believe I hinted last week at something of this nature being probable. The fact is that, as the term of the controlling patents runs out, the telephonists now commanding the situation become more and more apprehensive as to business competition, and less and less desirous of spreading information which may be of any benefit to their coming rivals. On the other hand, the fact that the Convention wishes to sit with closed doors makes many curious people resolute to find out what was actually done, and arouses various suspicions in the minds of

Digitized by Google

the public, which in this country, at least, is not at all inclined to look with a kindly eye upon anything like monopoly. The upshot of the affair was that the Convention excluded members of the Press, but furnished them with copies of the Papers read. In regard to one of these Papers, that on long-distance telephony, it seems to have been the desire of the Executive Committee, for some reason or other, that it should not be printed, but so far as the wishes of the authors could be ascertained, it is said they were very much in favour of publishing the Paper on which they had bestowed so much time, and hence the newspapers have taken the bull by the horns and printed the Paper. It is, of course, hard to please both parties in such a case as that, and perhaps the best and only thing to be done is to print the Paper, which seems to be a valuable and inoffensive addition to the literature of telephony. No stenographic report of the discussion was furnished to the papers, although this does not appear to have been a very severe loss, but in respect to the banquet the Executive Committee very kindly relaxed their harsh rule, and handed out to the papers a full and overflowing report of their post-prandial eloquence.

The Paper dealing with long-distance telephony was written by Mr. A. S. Hibbard, J. J. Carty, and F. A. Pickernel, three of the brightest young telephone engineers that we have. It enters very fully into details of long-distance work and the construction of metallic circuits, and discusses also the various changes that may be necessary in order to bring the local telephony into scientific and harmonious adjustment to the new long-distance business, which is becoming rapidly a very important factor in the transmission of intelligence all over the country. An interesting little Paper was read by Mr. R. M. Bailey on the subject of telephone salutation, in which he objected to the universal "Hello," and suggested that some form of introductory remark more suave and polite might be adopted. He pointed out that there was altogether too much "helloing," which took up time and did not by any means assist the coming together of the two parties anxious to begin talking, and he also criticised the excessive ringing of call bells, which is very much of an annoyance in offices where telephones are placed. Mr. E. H. McFall, of New Orleans, presented a pithy little Paper on the subject of the interference with the telephone circuits in New Orleans by the alternating-current circuits put in operation there. Mr. McFall did not state it in his Paper, but I believe the subject has become a matter of litigation. Mr. McFall says that the humming over the telephone circuits resulting from the interference is as strong and vigorous as ever, although various remedies have been tried. Several other members of the Association are suffering in the same way. In some places a compromise has been resorted to as to the bearing the expense of making the telephone circuits metallic, or in taking the heavy current wires along some other route; but in several instances, as for example in Cincinnati, there is litigation over the subject. In a great many of the larger cities it is only a question of time with the telephone companies as to the adoption of the metallic circuits reducing these injurious extraneous influences to a minimum, but in many of the smaller communities there will be trouble, unless the various companies giving the different services can come to some kind of amicable arrangement on the subject. Mr. W. D. Sargent, who has been elected President of the Association for the current year, read a brief Paper on the telephone exhibit at Paris, embodying a few observations on what he had seen in Europe while in charge of the Bell Telephone exhibit at Paris, and stating his impression that we have little or nothing to learn from abroad with regard to the operation of the telephone, or the carrying out of underground work. With regard to London, Mr. Sargent stated that he found the telephone system there to be entirely overhead, and that in Trafalgar-square he saw a large lead cable stretched along one side of the square in full view from all points. A report of a statistical nature, presented by General C. H. Barney, the Secretary, stated on this point that out of 48 exchanges reporting only eight have had experience in underground work, namely, New York, Brooklyn, Boston, Detroit, Pittsburgh, Buffalo, Washington and Louisville. New York City has the longest underground conductor, one over five miles in length, and has the greatest mileage of underground wire, 7,034 miles. The exchange at Pittsburgh claims to have had conductors working successfully underground since they were first laid there, seven years ago. A few other statistics from this report of General Barney are interesting. Thus, Boston, for instance, shows a gain of 48 per cent. in the number of subscribers last year, running up from 2,288 to 3,386. The average gain of the exchanges is about 8½ per cent. Grand Rapids has one subscriber to every 27 inhabitants, Portland, Oregon, has 1 to every 30, Providence 1 to every 49, New Orleans 1 to 188, Brooklyn 1 to 220, and Philadelphia 1 to every 309. Some of these subscribers manage to get the worth of their money out of the exchange, as, for example, at Richmond, where the average is 17·01 calls per subscriber per day. Atlanta, Ga., has nearly as many with 14·3. New York has only 7·8, while San Francisco actually reports only 1·6. It appears that in the majority of the exchanges the operators are busier this year than they were last, and several of them show a slightly increased cost per connection. It may be interesting to some of your readers to know that in 47 exchanges, with 1,435 operators, the highest average salary, including the chief operator, is £5 per week, the lowest is 18s. 9d., and the average is 23s. 9d. In 47 exchanges with 268 men, the average daily pay for linemen is 8s. 3½d., and for instrument men 7s. 6d., and for "combination" men 8s. 2d. I presume that these rates compare favourably with those paid in England, and they are pretty good pay, although in no instance will they lead to the rapid accumulation of wealth.

We have been following in this country with considerable interest the movements of Mr. Edison in Europe, and it has been a matter of gratification to everybody to witness the honours paid to him. It is felt that these honours are paid not simply to Mr. Edison as a great inventor, but to him also in his typical and representative character; and every such compliment adds, therefore, to the links of friendliness and esteem between America and Europe. It is believed in some circles here that Mr. Edison is contriving, in the intervals of sightseeing and being seen, to pay a little attention to business, and on this point the correspondent of the *Boston Herald* in London sent over the following curious piece of information, which I cannot do better than give you in full. You will probably be better able to judge of its worth than we are, and as to whether England would care to enforce with any colony any special reserve right except for weighty reasons:—"Frank Upton, president of the Edison Electric Lamp Company, at East Newark, and Eugene H. Lewis, of New York, who were with the Edison Party in Paris, arrived in London this week, and Upton sailed on the 'Saale' Thursday. Lewis, who is Edison's lawyer, and has conducted most of his recent patent suits, remains here to meet Edison and Evarts, a circumstance showing that Edison has changed his plans, and will come to London, and that he is to be accompanied by Mr. Evarts, whose ostensible purpose in visiting Paris was to have his eyes treated by an eminent French oculist. This gives rise to a rumour affecting electric lighting interests in America. The rumour is that Edison and the two lawyers visited London for the purpose of having a consultation with Her Majesty's Ministers about the prospect of Canada being included in the Patent Convention of 1883, which governs the patent laws of the United States and Great Britain, with a view to its effect upon Edison's high-resistance filament patent now in litigation in Canada. England reserves the right by the terms of this Convention to include any of her colonies under its provisions, and the clause that is supposed to interest the Edison people provides that the importation of a patented article from one of the States bound by the Convention to another shall not invalidate the patent. The filament patent was first taken out in Canada, and according to Canadian law an article patented in that country and manufactured in another country cannot be imported into Canada without invalidating the patent. Whether the Edison filament patent has been thus invalidated is now being considered in the Canadian Courts, and the representatives of other American electric lighting companies who will be affected by the decision believe that an effort is to be made to bring Canada into the

Digitized by Google

Convention that binds Great Britain in order to take advantage of the clause giving the right of importation between the States bound by the Convention. This would, at least, give an opportunity to gain time by bringing an intricate legal question into the Courts. Lewis professes utter ignorance of any such move on the part of Edison and Evarts, however." In the meantime, it may be stated, that the Edison people are pushing their business very successfully and vigorously in Canada, and that they are greatly increasing their facilities for manufacturing their apparatus in the Dominion.

An interesting description has just been published of the Hall electrolytic process for the production of aluminum now being carried out by the Pittsburgh, Pa., Reduction Company. The process is a direct one, and consists of the electrolysis of the oxide alumina from which the metal is produced pure in one operation, when all that is necessary to render the metal ready for sale is re-melting and casting. A fused bath is employed consisting of metallic fluorides which are less easily decomposed than aluminum, and have a lower specific gravity than the reduced metal, which sinks to the bottom of the bath, and is thus prevented from re-oxidation. The ore, or alumina, is dissolved in this bath, being decomposed by a low volt current, the oxygen going to the positive pole, and the aluminum to the negative. The current serves also to keep the bath melted. Each of the two pots in which the reducing operation is now carried on is about 24in. square and 20in. high, and is heavily lined with gas carbon. The pots are connected in series; each takes from 8 to 10 volts, being fed with current from two large dynamos developing 20 volts and 1,800 amperes, and contains a fused bath of from 200 to 300 pounds of the electrolyte. Three-inch carbon cylinders form the positive electrodes, and the gas carbon lining forms the negative. From each of the pots, as thus constructed and operated, a pound of metal per hour is obtained, and the ore is added in small quantities as required, so that the process may be kept up continuously day and night without interruption. A modification of this process has been worked out for the manufacture of aluminum bronze, in which with the same bath the electrodes, instead of being of carbon, are of copper. One of the great recommendations of this Hall process is that it is direct, and the claim is made for it that it is comparatively very cheap, while the product is excellent in its purity.

I have already given you sundry notes with regard to the late meeting of the American Association for the Advancement of Science at Toronto. I may now add, as of interest, that a Paper was presented by Prof. G. F. Barker, of Philadelphia, on a new form of storage battery. It is a zinc peroxide of lead battery, which is said to have been under test for the last two years, and which promises good results. The negative plate is composed of well amalgamated zinc and copper riveted together. No E.M.F. is set up between two such amalgamated plates. The positive plate is built up of a large number of thin lead plates covered with graphite, and riveted together with lead rivets about an inch apart. The compound plate is then perforated with numerous small holes. The graphite keeps the plate apart, and allows the solution to penetrate into every portion, so as to reach the entire lead surface. The electrolyte is an acid solution of zinc sulphate. No active matter in the form of lead oxides is applied to either plate; but the positive is strictly a Planté plate of very large surface. During the charging process the positive is peroxidised, and metallic zinc of a beautiful crystallised appearance is deposited upon the negative. These cells show an enormous increase in storage capacity per pound of metal, as compared with cells of the Faure type. A table of comparisons with several other cells was given, which exhibited the superior storage capacity of this new claimant. The new cell permits any rate of charging and discharging, and is exempt from the usual dangers of sulphating; in fact, in this respect it resembles the original Planté, which is much less liable to suffer from rapid discharge or from exhaustion than the Faure form.

The American Institute of American Engineers has resumed its meetings, and the first Paper of the present season was read last week by Lieut. F. J. Patten, U.S.A., on the subject of alternating-current motors. This has been his special work for some time past, and he certainly seems to be securing some decided advance in the direction of the utilisation of power transmitted long distances by the alternating current. The new motor which he described is self-starting. It is at first similar to an ordinary continuous-current motor on an alternating circuit. When the synchronism is attained, although a true alternating current flows, it traverses the two parallel circuits of the armature always in the same direction, maintaining constant polarity, this end being attained by a very simple method of armature connection. The re-directed current is also caused to traverse the field current. The Paper was subjected to a lively discussion, but the pith of the criticism was that Lieut. Patten made a distinct advance in a direction different from that in which Mr. Tesla and others have been working, and one which may lead to very desirable results. One of the objections advanced was that the consumer might find himself exposed to the danger of the high-tension current in the main wire, but, of course, if this objection holds it would apply also to series motors on arc circuits, and we have a great many such motors operating safely and successfully in this country. Some of the members seemed to think that it was best to strive for a motor without commutator or brush, but Lieut. Patten succeeded in convincing his audience that there were other features worthy of consideration.

CORRESPONDENCE.

THE DEFINITION OF IMPEDANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have just seen in your issue of September 20th, page 486, a statement with regard to the Resolutions of the recent Paris Electrical Congress, as modified by the Electrical Standards Committee of the British Association, which calls for a correction from myself. The Committee have adopted the term "impedance" instead of "resistance apparante." The term "resistance fictive," mentioned in your Note does not, I think, occur in the resolutions agreed to at the full sitting of the Congress on August 31. The term "impedance" is defined by us in exactly the same way as "resistance apparante" in the French resolutions; it is the ratio of the effective electro-motive force to the effective current, so that, in symbols, impedance

$$= \frac{\sqrt{\frac{1}{T}\int_0^T E^2 dt}}{\sqrt{\frac{1}{T}\int_0^T i^2 dt}}.$$

In the case of a simple harmonic electromotive force of frequency $n/2\pi$, the right hand side takes the well-known form $\sqrt{\{R^2 + L^2 n^2\}}$, but the term impedance is not defined by this expression, as would appear from your Note, but by the more general one above.

I hope to send you shortly a copy of the report of the Committee, which is at present in the hands of the printer.—Yours, &c.,

R. T. GLAZEBROOK,
Secretary Electrical Standards Committee.

Cambridge, Oct. 1, 1889.

[We are glad to have this correction; but in justice to ourselves we must add that our attention was especially called by a member of the Committee to the alleged difference of definition to which we referred in our Note.—ED. *E.*]

IRISH'S ELECTRIC PRINTER FOR NEWSPAPERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your issue of the 6th instant first to hand an editorial having reference to the Electric Printing Telegraph of Mr. H. T. Higgins and Messrs. Wright and Moore. Permit me in fairness to Mr. W. E. Irish to call your attention to the

Digitized by Google

enclosed description of his "Column Type Printing Telegraph," which was published early in 1883, five years prior to the invention by Messrs. Higgins, Wright and Moore. The printed matter is from a catalogue published by Weedon and Irish in 1883 or 1884. The same machine is mentioned by the *Railway Supplies Journal*, May 1, 1885.

These facts may be the means of preventing the threatened litigation you refer to between the more recent inventors of the "Column Type Printing Telegraph."—Yours, &c.,

Cleveland, Ohio, Sept. 18, 1889. W. M. MONROE.

[COPY.]

"This apparatus and machinery consists of a keyboard having keys representing two alphabets, with the necessary numerals and punctuation signs; a cylinder for carrying the paper upon which the first impressions are made, and a clockwork for propelling the cylinder, and another clockwork for actuating the communicator. A reporter seated with the above apparatus and his manuscript before him manipulates the keys and *prints the matter upon the paper, which is the width of a column of the paper he represents. When the columns are thus printed, they are by the compositors secured in order to an iron or stone slab* the size of the newspaper to be printed, and representing any number of pages. On the printing roller being passed over the printed paper the ink leaves the paper, having affinity for the roller, upon which it sets hard. The inker now passed over the originally printed paper leaves ink only where the paper had previously been printed upon, from which another printing roller takes the matter; thus a second and a third impression may be obtained as previously described upon rollers in duplicate. Two printing rollers, each representing one side of the paper, are now caused to revolve one beside the other with inkers revolving upon them. Between the printing rollers sheets or a continuous ribbon of paper the width required is passed, so that every revolution a paper is printed and severed from the ribbon, where such is used, and falling into a receptacle comes out a folded printed paper. For the printed matter transferred to the rollers in the first instance a specially prepared ink is employed. This ink leaves the paper freely for the printing roller, on which it quickly dries and sets hard. This hard ink type takes up ink freely from the inkers, but the other portion of the printing rollers rejects it. By means of this apparatus a newspaper may be printed in one quarter the time now occupied with one third the staff. The type wheels, which have various forms of type, are interchangeable, so that any description of printing may be done by one machine.

[We print our correspondent's communication in full, as it reaches us, but for our own part we fail entirely to see what possible bearing Mr. Irish's invention, so far as it is here described, can have upon the invention of Mr. Higgins or of Messrs. Wright and Moore. Mr. Irish seems to have had a totally different object in view.—ED. *E.*]

PROF. PERRY'S VOLTMETER.

TO THE EDITOR OF THE ELECTRICIAN.

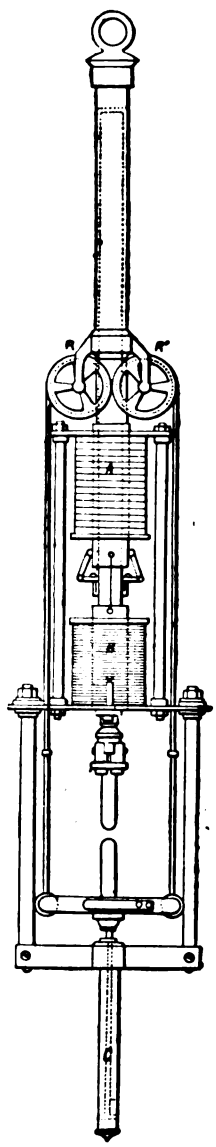
SIR: I was as much interested and surprised a short time ago as Mr. Evershed evidently now is to hear that Prof. Perry had devised, and succeeded in perfecting, a voltmeter on precisely the same lines that Mr. Evershed and I constructed one three years ago. We gave it up, as Mr. Evershed has said, on account of the excessive power which seemed necessary to work it. Prof. Perry was kind enough, a month or two ago, to show me his instrument, which it certainly seems he has succeeded in making into a very good voltmeter. By using a very thin and narrow strip of platinum silver only a few inches in length, with a wire resistance in series with it, he has produced an instrument which, so far from taking forty amperes to work it, does not take any more power than an ordinary Cardew voltmeter. Prof. Perry also finds that he can artificially "tire" the spring so that it will always, though slowly, return to zero. I believe, however, that some difficulty may occur in compensating the spring—especially when made of carbon—for variations in external temperature. The use of such a spring is evidently not confined to voltmeters. Prof. Perry has a weighing machine constructed with one. The motion of the spring is very pretty, and no doubt "vastly simple," but all the same I believe the mathematics of it have not yet been discovered.—Yours, &c.,

Oct. 2, 1889. GILBERT S. RAM.

THE KREMENESTSKY ARC LAMP.*

The Kremenestsky lamp consists of two solenoids, A and B, wound respectively with thick and thin wire; two soft iron cores connected by levers, as shown; two rods serving as guides to the negative carbon holder, which is supported by two cords wound round the pulleys R R'; an air dash pot, C.

If the lamp is switched into circuit with the carbons in contact, the solenoid A attracts its core, pushing up the positive carbon holder, thus striking the arc. When the lengthening of the arc increases the action of the solenoid B, the lower core is sucked downwards, the levers extend, and the positive carbon descends, causing the negative carbon at the same time to rise. The arc diminishing, the action of A again preponderates, and so on.



This lamp does not work as regularly as the Pilsen, because the equilibrium between the counter weights and the solenoidal attractions is not exactly realised in every position of the rods.

COMPANIES' MEETINGS & REPORTS.

The Direct Spanish Telegraph Company.

The thirty-second ordinary general meeting of the Company was held at Winchester House, Old Broad-street, under the presidency of Sir James Anderson.

The MANAGER (Mr. C. Gerhardi) read the notice convening the meeting and the minutes of the last ordinary general meeting, which were confirmed as correctly entered. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I think you will regard the report as, on the whole, fairly satisfactory. There is a decided increase in our traffic—£508—and a slight decrease in working expenses, perhaps not worth mentioning, but still it is a decrease, and with an increase of traffic and a decrease of expenses no one can find fault. As you know, we had in the half-year to which the report refers an interruption of sixteen days of the Bilbao cable, but, fortunately, we have a joint purse arrangement with the Eastern Telegraph Company, and the losses of traffic by these interruptions are never very serious. I am glad to say that our revenue is mainly due to commerce. There were no political disturbances of any kind that gave us any telegrams. We find, on looking into matters, that many towns in the United Kingdom which now have a very free intercourse with Spain by telegraph never used the telegraph a few years ago, and therefore, I suppose, they had no trade with Spain. We are led to believe, or to suppose, that the trade of our country has increased with Spain, and that must be matter of general congratulation to us all. Last month alone we carried 2,920 more telegrams and 31,200 words in excess of the number carried in September last year; and for the past quarter—July, August, and September—our receipts were £381 in excess of those of last year, notwithstanding our low tariff. I suppose you all know that our tariff is very low—4½d a word. We deliver our messages in Bilbao under ten minutes—very often in five minutes; and in Madrid they are delivered a good deal within the hour—I am told three-quarters of an hour, and we hope to improve that. All telegraphic service depends, first on accuracy, and then on speed, and we are increasing the speed as far as we can, getting better wires from Bilbao to Madrid and Barcelona. So far as Madrid is concerned we have very little to complain of—in fact, we do not complain, but still there is room for improvement. We have still to count with the reduction of the length of the messages, and I scarcely know where this is going to stop. The reduction has been going on at the rate of nearly a word every year. I do all I can to persuade myself—I hope justly—that though the length of the messages decreases their number increases. I saw just now that last year I told you, as I did the year before, that though we carried more messages we made less money; but we have now got over that, because this year we have made more money and carried more messages. Therefore, I hope it is fair to infer that the reduction in the length of the messages has come to a stop, and that that being so we shall get more revenue. The only thing I have to call attention to in the way of expenditure since the expiration of the half-year of which I have been speaking is that we have removed our London Telegraph Station from Leadenhall-street. Owing to the increase of our business we became very crowded there, and we have taken larger offices in Gracechurch-street. The cost of this removal, not including the shifting of the pneumatic tube, we estimate at about £600. We propose, however, to take that amount from revenue gradually, and not to add it to capital. I have now told you all that is worth telling. The report is very simple, and I think that a small report and a big dividend is about as good a combination as a shareholder in any company can have. I now propose,

"*That the report and accounts now presented be and are hereby received and adopted.*"

Mr. EDMUND ETLINGER seconded the motion.

The CHAIRMAN: If any gentleman has any question to ask I shall be glad to answer him.

Mr. COCHRAN inquired the meaning of the entry in the balance-sheet—suspense account, £260. 14s. 10d.; and he also desired to know what difference in the rent the change in the offices would cause.

The CHAIRMAN: About £80 a year. The suspense account is mostly composed of items expended on account of the removal, but not appertaining to last half-year. The rent is higher because the premises are more important. We put up formerly with very small premises. He put the motion, which was carried unanimously. Continuing, he proposed the following resolution:—

"*That the dividend at the rate of 10 per cent. per annum, less income tax, on the Preference Shares, and a dividend at the rate of 5 per cent. per annum, free of income tax, on the Ordinary Shares, both for the half-year ended 30th June, 1889, be, and are hereby declared.*"

Mr. ETLINGER seconded the motion, which was carried unanimously.

The CHAIRMAN having intimated that that closed the business of the meeting,

Mr. COCHRAN proposed a vote of thanks to the Chairman and Directors for their conduct of the Company's affairs, the general result being, he thought, eminently satisfactory.

Mr. LOWE seconded the motion, which was carried unanimously.

The CHAIRMAN: I am very much obliged to you for the confidence you have expressed in my colleagues and myself. We have not a long story to tell about hard work, and we have not had much of that in the past half-year. Still, the traffic requires looking after, or it would slip away elsewhere, and it is necessary that the Company's officials should steadily look it up. I hope it will be a long time before I have to make a long speech to you, as that generally means an interruption of the cable or something we do not like.

The proceedings then terminated.

Electric Construction Corporation.

The first ordinary (statutory) meeting of the Electric Construction Corporation (Limited), was held on Friday last, at the offices of the Corporation, Worcester House, Walbrook, Sir Douglas Fox, J.P., presided.

The SECRETARY (Mr. F. Walton) having read the notice convening the meeting,

The CHAIRMAN said—Gentlemen, as you are aware, this is our statutory meeting; therefore we have no report to present to you, nor are there any resolutions to be proposed; but I need hardly say that it is a great pleasure to the Directors on this, the first occasion, to be able to meet the shareholders face to face, and to exchange a few ideas with reference to the present position, and the possible future of what we believe to be a most important Corporation. I may say, to begin with, it is perhaps a most important point—that all our capital was fully subscribed, and I do not think you could easily find a company of this size whose capital is more strongly held than ours is at this moment. Another point, which is very important, is that our works are fully occupied. We have as many orders as we can execute, and we could easily have a great many more if we could only execute them. I think, as you look at the gentlemen on my right hand and on my left, you will feel that there are practical men amongst us, and we are naturally inclined to be cautious in what we do; at the same time, our chief difficulty at this moment is that we have not room enough in our works to enable us to extend our business as we should wish. The consequence is that the first attention of your Directors has been given during the few months which have elapsed since this Company was formed to laying out very carefully and preparing to immediately erect extensions of our works at Wolverhampton. I am glad to say that, by the assistance of the gentlemen who are thoroughly well acquainted with Wolverhampton, and who have given an immense deal of time to this matter, we have been able to secure an excellent site there, with good railway and canal communication, ample not only to provide for a very large extension of our business at the present moment, but also to provide for the future. Upon that site we intend immediately to erect works which will enable us to very largely increase our output at Wolverhampton. I am very glad to tell you also that in connection with the accumulator business of the Electrical Power Storage Company there is a steady growth, and when we are able to combine all the business, as we intend to do, in this office, and to have all our arrangements at headquarters, you will see that that will form a most valuable adjunct to the general business of the Company. It is not very often, especially at this time of the year, that we get such a good attendance of shareholders at a statutory meeting, but we were rather anxious that our shareholders should meet us in our own offices on the first occasion, rather than that we should

Digitized by Google

go to some hotel, and if the room is rather crowded perhaps you will excuse us. You will probably be aware that we are engaged at the present moment in supplying a very large quantity of plant to one of the most important companies that is supplying this metropolis. I think you will be interested to hear that Mr. Edison, who has just had an opportunity of visiting one of the installations with which we have had to do in this metropolis—namely, Rathbone-place—was pleased to say that it was the most satisfactory place he had seen during his visit here, and I am quite sure that the high character which our Works' Director at Wolverhampton has secured to us by the excellent work he has been able to turn out will be a most important factor in the success of this company, if only we can provide him with works large enough and with sufficient means to enable him to execute the orders which are pressing upon us on every side. Then, with reference to provincial questions, I do not think it would be wise—and I am sure the shareholders will agree with me in this—to mention names at the present time, because our business in that direction is somewhat in a preliminary stage. We are carrying on very active negotiations with several most important towns, both with reference to lighting, in which, I think, this Company is going to fill a very important position, as being able not merely to provide these towns with light, but to help in the financial arrangements connected with lighting. I think that is where we are going to have a very important sphere of business; and then not only with reference to lighting, but also with reference to the application of motors to tramways. We have got several very important matters before us, and we hope that before long we shall be able to show our shareholders a practical installation of this kind, where we shall be able to run the tramways by electricity in the very successful way in which they are being run so largely in the United States. We have applications both with reference to our Julien patents and to our Sprague patents. Then I may also say that with reference to the third point to which we attach importance—that of the installation for train lighting—a very excellent example has just been carried out by the Midland Railway Company upon the Stroudley-Houghton principle, and I believe that although it is only just started, it is likely to be a very great success. The great difficulty which has arisen with reference to train installations has been how to replace the power, and I think the arrangements which are being made in connection with this train on the Midland are very likely to solve that difficulty. The great requirement for railway installations is that we should be able to light a train and be able to break it up. That has been done successfully on the Brighton Railway, but what we want is to light the train and be able to take a carriage off and shunt it on to a branch line. I do not know that I have anything more to say to you to-day, gentlemen. If there is any question any shareholder would like to ask I will endeavour to answer it to the best of my ability. Our difficulty at the present moment is simply this—that our works are quite insufficient to deal with the orders which we can secure at once, and therefore we are obliged to proceed rather cautiously; at the same time, I think we are laying the foundation of an excellent business. I may say we have secured here offices which will not be at all too large for our purpose, and we hope you will consider that they are in a good central position. And in connection with these offices we intend to have a thorough good arrangement in the base where our various manufactures will be placed so that intending purchasers, and those in this city who intend to adopt electricity, will be able to come and see exactly what we are prepared to give them. It has been found very important to do this in connection with the Electrical Power Storage Company, from which we believe we shall secure a good deal of support. Before long we shall have a general meeting, and then we shall hope to present a regular report. In the meantime I must ask you to be content with this very lame attempt to explain to you exactly how we stand.

A SHAREHOLDER: Do we understand that in regard to each branch of the undertaking the works are in full swing?

The CHAIRMAN: They are.

A SHAREHOLDER: And doing as much work as the accommodation permits of?

The CHAIRMAN: They are doing more work than we like to have to do in their present contracted condition. We are losing no time, however, in extending the works, which is the important thing.

Dr. DRYSDALE: Do you expect to have some tramways running in London?

The CHAIRMAN: Well, I cannot speak about London; I spoke about provincial towns. We have several provincial towns in which there are actual arrangements being made; I would rather not mention the names at the moment, but I have no doubt before very long you will know al about them.

Dr. DRYSDALE: Is there no chance of London?

The CHAIRMAN: I don't know; I think it is quite possible, but I cannot speak with certainty. We hope that before long we shall not only apply ourselves to the traction question for tramways, but to a far more important question to my mind, and that is railways. I hope that electricity will be applied in the case of railways, and if we once begin I don't know where we will end; but just now we are satisfied with the tramways.

Mr. ROBERT CHIPPERFIELD asked if it was true that the enormous demand far exceeded the power of supply, and, if so, how it was that four, at least, of the concerns they had purchased paid no dividends. If that was the case, was the sum of £400,000 or £500,000 not an enormous amount to be expended in establishing such a company as this, especially when they reflected that similar undertakings had more or less come to grief. He also wished to know on what basis the several purchase considerations were arrived at, and if the promotion money paid in purchasing the several undertakings amounted to something like £150,000. He believed the Elwell-Parker concern was the only one of the companies that paid a dividend. The prospectus stated that it paid a "substantial" dividend. It would be more satisfactory to know what the "substantial" dividend was. He wished, also, to know whether they had contracts for supplying light to the trains spoken of, or whether they simply obtained permission to make experiments, there being no contracts at all. He further asked what expenses they intended to incur in extending the works, and whether, when all the capital was called up, it would be sufficient to carry on all the business of the Corporation for the present without calling up the remaining £50,000.

The CHAIRMAN said the amount of capital was £500,000, of which £50,000 was taken in part payment by those who had sold their businesses to the Corporation; therefore, the actual amount issued to the public was £450,000, out of which they had called up £6 a share, and £4 a share was still uncalled, and remained as an asset to enable them to carry on their work, and to make all their payments. That amount of £500,000 left made a considerable balance for working capital. He sincerely trusted that it would not prove sufficient, or anything like sufficient, for what the Corporation would have to do. His opinion was that it was only the first instalment—if they succeeded as they expected to do—they would have to raise more money; but it was an ample amount for dealing with their present liabilities and providing them with working capital. There were certain questions of detail; for instance, the works at Wolverhampton, which he thought should be left over till the next ordinary meeting. They might be quite sure that the Directors would be very careful not to expend money unless they thought that it was going to produce a thoroughly good result. The present need of the Company was extended works at Wolverhampton, and if they had them now they should be very lucky, because they could fill them with most profitable work immediately. He did not feel inclined to go into some of those questions which affected the original arrangements made, because all these matters were fairly put before the shareholders when the prospectus was issued. It was impossible for him to say what was paid for promotion money. What they did was to purchase the properties for a certain payment, and whether that payment included

money to other people they had not the means of knowing. All he knew was the amount they were bound to pay to the vendor, Mr. Tarver, and that they meant to pay, and then he hoped they would be able to pay a good dividend on it in due course. He was told that Elwell-Parker paid dividends varying from 10 to 15 per cent.; and with reference to the other companies, he thought the point had been lost sight of by the gentlemen who had been speaking, that the great stepping-stone to success in this Company was the amalgamation of these different interests. He did not think these companies standing by themselves would be worth what the Corporation was paying for them; but the point was this: they were amalgamating those interests and forming a strong buttress against opposition, and the patents which they held became extremely valuable.

Sir DANIEL COOPER, Bart., said he had had to do with the railway lighting for the last five or six years, and he might state that all the contracts for lighting the different railways were written contracts. They had to give them 12 or 18 months at a certain price, so that the officials could judge for themselves whether the companies ought to take the lighting up or not. The officials wanted to be certain that they had got a good thing, and as the Directors knew it was a good thing they gave them all the facilities they could, and that was the only way he thought to promote the business of the company. He belonged to one of the companies whose business had been purchased by this Corporation, and he knew they had got a good bargain. He did not see how, if the Corporation was carried on with skill, and with a proper Board of Directors, it could fail to be a great success.

Mr. GEORGE DIBLEY proposed a vote of thanks to the Chairman for presiding.

Mr. CHIPPERFIELD seconded the motion, which was unanimously agreed to.

The CHAIRMAN acknowledged the compliment, and the proceedings terminated.

NEW COMPANIES REGISTERED.

THE ELECTRICAL ACCESSORIES COMPANY (LIMITED).—Registered by W. T. Cooper, 29, Essex-street, Strand, W.C., with a capital of £5,000 in £1 shares. Objects: To carry on the business of electricians, gas and general lighting engineers, &c.

HAMILTON GRIFFIN AND COMPANY (LIMITED).—The company was registered on the 24th inst., with a capital of £20,000, divided into 5,000 A preference, 5,000 B preference, and 10,000 ordinary shares of £1 each, to transact business as general and financial agents, and to apply for concessions and other powers for the construction and maintenance of railways, tramways, telephones, electric light and power systems and waterworks, in any part of the world.

JOHN WILD AND CO. (LIMITED).—This company has been registered with a capital of £10,000 in £5 shares, to carry on the business of mechanical and electrical engineers, steam, gas, and air engine makers, iron and brass founders, &c. Registered without articles of association.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended September 27, 1889, amounted to £2,867.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of September, 1889, were £2,400, as compared with £2,774 in the corresponding month of last year. The receipts for the month of June, estimated at £3,300, realised £3,397.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of September, 1889, amounted to £40,418, and to £41,095 in the corresponding period of 1888, a decrease of £677.

EASTERN TELEGRAPH COMPANY (LIMITED).—This company announces the payment, on the 14th October next, of interest at the rate of 3s. per share on the Preference Shares of the Company, less income-tax, for the quarter ended 30th September, and an interim dividend of 2s. 6d. per share on the Ordinary Shares, free of income-tax, in respect of profits for the quarter ended the 30th June last. The register of transfers will be closed from the 7th to 14th October, both days inclusive. The traffic receipts of this company for the month of September amounted to £51,881, and to £49,273 in the corresponding period of 1888, showing an increase of £2,608.

ELMORE'S FOREIGN AND COLONIAL PATENT COPPER DEPOSITING COMPANY (LIMITED).—The first general meeting of this Company will be held at the Cannon-street Hotel, E.C., this day (Friday) at 12 o'clock noon, for the purpose of transacting the ordinary business of the Company. An extraordinary general meeting will be held immediately after the general meeting, when resolutions, rendered necessary in order to comply with the requirements of the Stock Exchange before that body will give the Company a special settlement and official quotation of its shares, will be proposed. Should the resolution be passed by the required majority, it will be submitted for confirmation as a special resolution at a second extraordinary general meeting, of which due notice will be given.

SUBMARINE CABLES TRUST.—Notice is given that on and after the 15th inst., the coupon due in April last will be paid in full by Messrs. Glyn, Mills and Co., of Lombard-street, between the hours of 10 a.m. and 2 p.m. The coupons must be left with the bankers for examination four clear days before payment. Certificate holders are requested to present the coupons for April, 1889, only, and not those payable on October 15th, 1889.

TELEPHONE COMPANY OF AUSTRIA.—This Company has declared the usual half-yearly dividend to 30th ult. on the preference shares at the rate of 6 per cent. per annum, payable early in October.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended September 27, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £1,623.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this company for the month ended 30th September, 1889, amounted to £7,250.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this company for the half-month ending September 30 amounted to £2,206, as compared with £2,050 in the corresponding period last year, showing an increase of £155. Receipts for the month of June, estimated at £5,907, realised £5,908.

BUSINESS NOTICE.—Our contemporary *Electrical Plant* announces that they are about to open as store rooms premises situate at 39, Queen-street, E.C.

CHANGE OF ADDRESS.—The Westinghouse Company has removed its offices and show-rooms from Gresham House to 4, Victoria Mansions, Victoria-street, S.W.

LEGAL.—THE UNITED TELEPHONE COMPANY (LIMITED) v. NORTON AND COMPANY.—Mr. Justice Denman made an order at the last sitting of the Vacation Court committing Robert Norton, who trades as Norton and Company at Manchester, for contempt in disobeying an injunction made against the firm in 1884. Upon the Registrar being applied to to draw up the order it was pointed out that the original order of Mr. Justice Chitty had never been served upon the defendant, and the case was therefore mentioned to Mr. Justice Denman on Wednesday. Council representing the United Telephone Company urged that the order having been made by consent, and the defendant knowing all about it, service was unnecessary. Mr. Justice Denman said he should leave the matter to be dealt with by Mr. Justice Chitty. It was not a case of any special urgency.

——— In the Westminster County Court on Wednesday, Judge Bayley had before him the case of the Woodite Company *v.* Cole and Co. The action was brought to recover £5. 15s. from the defendants, who are electrical engineers, for certain battery cells made to the defendants' order. Mr. Joseph Weekes, assistant-manager to the company, said the cells were made in the very best way, and there was no fault with them. He explained that the Woodite Company was young, and they were doing their best to put the article before the public. The defence set up was that no order was ever given for any cells, and that the moulds were not made according to the pattern given. After hearing the evidence, his Honour gave judgment for the plaintiffs.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 595.—Vol. XXIII. FRIDAY, OCTOBER 11, 1889. Price Fourpence.

NOTES.

In our leading article this week we have compared the Colchester installation of 1884 with the Chelsea installation of 1889, with a view to discover the lines along which progress has been made. It is, however, of equal interest to compare with the Chelsea system the one other distinct method of storage battery distribution which has been put prominently before us. The Crompton system, as we all know, is essentially a multiple wire system, in which batteries are employed to maintain the balance in the different sections, the batteries, moreover, serving to provide for the supply during all the hours of light load. This system is, therefore, *primâ facie* the more economical of the two in so far that a portion of the current is supplied direct from the machine to the lamps, and thus escapes the heavy tax of at least 30 per cent. which is levied in transit through the battery. Another apparent advantage lies in the fact that in the normal working of the system there are no circuit changes to be made, —that is to say, the batteries are continuously connected on the one hand with the supply mains, and on the other hand with the charging mains, the whole being charged in series. The regulation of the difference of potential on the lamp circuits is, therefore, the only switching which has to be regularly performed. This is done by hand, a certain number of cells being switched in or out as required. There are still some points about this system which want further explanation—for instance, as to how the charging is regulated, so as to avoid both a cumulative differential treatment of the cells on the one hand, and waste of energy in over-charging on the other. What we are at present concerned with, however, is the prospective rivalry between an automatic and a non-automatic system, and it is much to be regretted that up to the time of our latest information the extension of the Kensington Court installation had not been such as to demand the introduction of sub-stations. We have, it would seem, no concrete example of the Crompton system anywhere nearer than Le Mans.

General Webber differs again from Mr. Crompton on the question of bare conductors. In 1884 he laid some uncovered copper cables on insulite saddles in cast-iron troughing, and although all due precaution seems to have been employed the result was a complete failure. We are not told *how* the failure was caused, but perhaps it is disclosed in the statement that the joints "were believed" to be water-tight, so that probably no provision was made for drainage. It cannot be too strongly asserted that, with bare conductors, success is hopeless unless the conduit is properly drained. It seems inconceivable that this point should be overlooked, yet mains of this class have been recently laid in London under conditions which, as Prof. Forbes remarked in Newcastle, render an explosion some day inevitable. We do not, however, fear such a catastrophe, as the Company in question must certainly before long open their eyes to the facts, even if they have not already done so.

We hear that the experience of the House-to-House Company as regards the insulation of their mains at the West Brompton Station continues to be highly satisfactory. It will be remembered that these are lead-covered cables laid in iron pipes. We have unfortunately forgotten the exact number of megohms per mile which the cables test up to, but it is a remarkably high figure. Speaking of lead-covered cables, it should not be forgotten that at Colchester this type of conductor was in use for over two years, under a tension of 1,250 volts, and never gave any trouble, although the conditions were of a peculiarly trying character.

It is impossible, we think, to deny that Prof. Ayrton (in the Paper on the "Practical Unit of Induction" which we publish this week) makes good his ground that 10^9 C.-G.-S. units, whether it be called a "quadrant" or anything else, is "neither the practical unit of induction, nor is it the secohm of Messrs. Ayrton and Perry." It is sufficiently obvious that the practical unit must have such a value as will fit into the fundamental equation when the other terms are expressed *in practical and not in C.-G.-S. units.* That the B. A. Committee meant the "quadrant" to be a "practical" unit is clear enough, and it would seem impossible to allow the matter to rest without some clearer understanding.

In our esteemed correspondent, Mr. T. H. Blakesley, we find another malcontent on this question of nomenclature. Mr. Blakesley declines to speak of impedance, and prefers the term "effective resistance." Without discussing the relative superiority of these phrases, we may be permitted to observe that Mr. Blakesley has apparently overlooked the fact that the hitherto accepted definition of impedance (up to the time of the late British Association meeting) explicitly recognised that the term related to circuits carrying sinusoidal currents. Mr. Oliver Heaviside (*Electrician*, June 17, 1887, p. 124), when introducing the term, says, "(I use) . . . . Impedance to express the ratio force/flux in the very important case of sinusoidal current."

Digitized by Google

Now certainly the case of the sinusoidal current has not diminished in importance since 1887. Not only has Mr. BLAKESLEY himself published a work chiefly devoted to the investigation of this particular case, but further experiment has shown that the currents in actual use conform to this special function to a degree which few ventured to anticipate. The British Association Committee, whilst adopting the term, has, however, widened its meaning, so that it shall signify in general "the ratio of the effective electromotive force to the effective current," as Mr. GLAZEBROOK wrote last week. Mr. BLAKESLEY thinks there is a slip of the pen in this sentence—but we do not follow him here. There are other points raised by our correspondent which we should liked to have commented on, particularly as we are able to see some force in the argument; but space is wanting.

IN connection with the Paris Exhibition awards, to which we referred in our last issue, we are informed that the Compagnie Générale des Lampes Incandescentes, of Paris, was awarded a gold medal for their exhibit of "Edison-Swan" lamps. Messrs. LAING, WHARTON and DOWN, who represented the Thomson-Houston Electric Company in the United States Section, obtained two gold medals—one for okonite wire and one for the Thomson-Houston system. A gold medal was also awarded to the Volta Graphophone Company, of Washington, for Tainter Bell's beautiful instrument, the Graphophone. It will be observed in the list of awards, which we published last week, that only one Grand Prize was granted to the English electrical exhibitors, the firm singled out for this gratifying distinction being Messrs. ELLIOTT BROTHERS. We may remark that the information contained in the official list of awards is very meagre, no mention being made of the particular exhibits for which the various awards are made.

ONE effect of the recent great strike has been to give a new impulse to the formation of trades' unions; and considering the dimensions which electrical industry has now attained it does not surprise us that the artisans employed in it are following the fashion. The reasons assigned are not as intelligible or as manly as we could have wished—one of them being that the electrical workman never knows in the morning whether he will return home in the evening alive, an uncertainty which most of us endure with perfect resignation. A good deal of the pernicious nonsense now prevalent among workmen about offering a united front to the money-bags of the capitalists was repeated at the Paul-street meeting—nonsense which, if the men are as intelligent as we should expect electrical workmen to be, they ought to forswear as soon as possible. The gist of the matter probably is, however, that electrical trades are in that prosperous condition which is generally the signal for a rise in wages; and on the whole, perhaps, this is not a matter to alarm us greatly.

WE understand that Mr. EDISON, during his recent visit to London, stated that he would shortly place on the market an incandescent lamp which could be retailed at less than one-half the price of the present lamps. He also affirms that for the same expenditure of watts per candle-power 25 per cent. more light may be obtained.

To abbreviate a name of twenty-eight syllables is undeniably a laudable operation if carried out with due care. When the name is that of a Committee of the British Association it is, to say the least, desirable that the short title should not mislead as to the character of the Committee. Now, at Newcastle, in the official documents of the Association, we found mention of the "Committee on the Magnetisation of Iron." Naturally we supposed, as did many others, that the Committee of Section A had undertaken to thrash out this enormously wide and vastly important subject; and in our issue of September 27th we expressed our disappointment and discontent with the report as actually read. It now turns out, as may be seen from our correspondence columns, that the Committee was appointed to investigate "Certain Molecular Phenomena associated with the Magnetisation of Iron, Nickel, and Cobalt." This being the case, our recent comments upon the report do not apply, and we withdraw them entirely. But why did the Committee allow itself to receive such a totally misleading designation?

Burnley.—The Corporation intend to apply for an electric lighting Order.

Oldham.—The Corporation intend to make application for an electric lighting Order.

Bolton.—The Corporation have decided to oppose all applications for electric lighting Orders.

Nottingham.—At a meeting of the Town Council on Monday last, it was decided to apply for an electric lighting Provisional Order.

Bangkok.—An electric light company has been established in Bangkok, the King of Siam holding 2,875 shares of the total issue of 6,900.

Segovia.—The machinery and fittings for the Segovia central lighting station have been ordered from Messrs. Julius G. Neville and Co., of Liverpool.

Tynemouth.—At a special meeting of the Town Council, held on Monday, it was decided by 12 votes to 4 to apply for an electric lighting Provisional Order.

Wigan.—The Corporation intend to oppose the applications of electric lighting companies only so far as may be necessary to protect the interests of the borough.

Derby.—A special meeting of the Town Council is fixed for the 9th prox., to pass a resolution in favour of an immediate application for an electric lighting Provisional Order.

The Lighting of the City.—A special meeting of the City Commissioners of Sewers has been called for Tuesday next to finally deal with the question of the electric lighting tenders.

Royal Victoria Hall.—We are asked to state that Madame Nordica will sing for the first time at the Royal Victoria Hall on Thursday, October 17th, when there will be a Grand Ballad Concert.

Rochdale.—The Town Council, last week, endorsed a recommendation of the Gas Committee that the Corporation should not themselves make application for an electric lighting Provisional Order.

Airdrie and Coatbridge.—At the last meeting of the Town Council it was unanimously resolved to advertise the Council's intention to apply for a Provisional Order to light the burgh with electricity.

Dundee.—At a special meeting of the Dundee Gas Commission it was resolved to apply for a Provisional Order empowering the Commission to supply the electric light for public and private purposes within the city.

West Bromwich.—The Gas Committee of the West Bromwich Corporation will recommend to the Council, at a special meeting, to apply for a License or Provisional Order authorising the local authority to supply electricity.

Digitized by Google

Kingston-on-Thames.—The Kingston-on-Thames Corporation have decided to apply, in conjunction with other neighbouring authorities, for a Provisional Order to enable them to supply electricity in the district for lighting purposes.

The Russian Telegraph Service.—It is reported (says *The Times*) that all foreigners at present engaged in the Russian Telegraph Service will either have to accept Russian nationality by 1st January, 1890, or to resign their appointments.

East Cowes.—At the last meeting of the East Cowes Local Board a letter was read from the Municipal Electric Lighting Company, asking the Board to support the Provisional Order for supplying Cowes with the electric light. No steps were taken in the matter.

Execution by Electricity.—The New York judge who has been hearing the appeal against the execution of Kemmler by electricity has given his decision that there is nothing unconstitutional in the proposed method, and it is said that the sentence will now be carried out.

Newport.—At the last meeting of the Town Council it was unanimously resolved to withhold the consent of the local authority to the proposed Provisional Orders of the various electric light companies until the subject could be considered by the Island County Council.

West Hartlepool.—At the last meeting of the Town Council it was decided to oppose the applications of the various electric lighting companies for Provisional Orders, on the ground that the Council had under consideration the desirability of itself applying for the requisite powers.

Bacup.—Last week a special meeting of the Bacup Town Council was held to take into consideration the expediency of applying for a Provisional Order to authorise the supply of electricity by the Corporation. It was resolved that the Council should apply for a Provisional Order,

Proposed Classification of Telegrams in France.—It is said that the Minister of Posts and Telegraphs is contemplating the adoption of the Dutch telegraphic classification, namely, fast, slow, and ordinary telegrams, with a view to relieve the pressure on the French telegraph system.

Tenders Open.—Tenders are to be sent by the 24th inst., either to the Chief Postal and Telegraph Department at Madrid, or to the telegraph office at Segovia, Spain, for the establishment and working of a telephone exchange in the town of Cora, in the province of Segovia.

Barnet.—At the last meeting of the Local Board a letter was read from Messrs. Joel and Co., to the effect that negotiations were in progress for transferring the lighting contract to the "United Gas Improvement Company," which own the English patents for the Heisler system of lighting.

Stockton.—At the monthly meeting of the Stockton Town Council, held last week, the town clerk and gas manager submitted a report upon the question of electric lighting, in which they advised the Corporation to apply for a Provisional Order authorising them to supply electricity within the borough.

Reading.—At the last meeting of the Reading Town Council the Highways Committee reported that they had considered the subject of arranging with Messrs. Laing, Wharton and Down for the lighting of a district of the borough with electricity, and thought it was not advisable to proceed with it at present.

Athens.—On the occasion of the marriage of the Crown Prince of Greece the streets of Athens are to be lighted by electricity. The contract has been given to the Edison Continental Company, who have sent out four 500-ampere Edison dynamos, and two 170 horse-power Weyher and Richemond engines.

Devonshire Club.—Very extensive alterations are being made to the club, including the introduction of the electric light throughout the building. Messrs. Drake and Gorham inform us that several new features in lighting are to be introduced, which they expect will be very generally adopted throughout the London clubs.

Electrical Engineering Appointment. — Mr. Alexander Stewart, who studied electricity at the Glasgow and West of Scotland Technical College under Prof. Andrew Jamieson, has just been offered an important position in the new shipbuilding yard of Messrs. Palmer and Co., at Bilbao, namely, that of naval architect and electrician for the works.

W. T. Henley's Telegraph Works Company.—We have received the September price list of electric light cables and wires of this well-known firm. The list contains full information with regard to the price, gauge, insulation, weight and resistance of the various sizes of conductors. Quotations are also made for electric light casings in American whitewood, redwood, and pine.

Falmouth.—The Lighting Committee of the Falmouth Town Council have had under consideration the question of electric lighting, and their recommendation, adopted by the Town Council, is that the Corporation and Local Board of Falmouth, the Penwerris Lighting District, and the Corporation of Penryn be invited to join in obtaining powers for supplying the district with the electric light.

Electric Traction on the South London Tramway Company's Lines.—An experimental trip was made last week by a Jarman electric car on the South London Company's line. It is expected that six of these cars will be running regularly in about a month's time. The distinguishing feature of the Jarman system is, it will be remembered, the employment of two separate motors mounted on the same spindle.

Croydon.—At the last meeting of the Croydon County Council, the following resolution was formally moved, and its consideration adjourned until the next meeting:—"That the Council do apply for a Provisional Order giving to the Corporation electric lighting powers for Croydon, and that it be referred to the General Purposes Committee to report as to the necessary details of the application."

The Institution Dinner.—The dinner of the Institution of Electrical Engineers will take place at the Criterion, Piccadilly, on Monday, the 4th of November, at half-past seven o'clock. Those who desire to attend must send in their applications to the secretary as early as possible. Should the number of tickets applied for exceed the accommodation available, the applications will be dealt with in the order of their receipt.

Electricity in Mines.—Electric traction is about to be introduced into some coal mines near Scranton, Pennsylvania. One mine will have an electric road over a quarter of a mile long. It is expected that a large saving will be effected. At present, 12 mules, with runners and drivers, are used to haul the cars from the head of the slope to the bottom of the shaft. Electric lighting will also be introduced at the same time.

The Striking of Trees by Lightning.—The *Elektrotechnische Echo* is responsible for the following explanation of why oaks are more frequently struck by lightning than beech trees. The leaves of the beech tree are, it seems, covered with a fine down, which is a better conductor of electricity than the smooth leaves of the oak. According to the same journal, experiments with discharges from influence machines tend to confirm this theory.

Cheap Telegrams in Hungary.—According to the *Daily News* correspondent at Budapest, the Hungarian Board of Trade is making plans for an important reform. The charges for telegraphic messages are to be organised afresh, and to be proportionate to the distance to which the messages are sent. Two kreuzers, or less than a halfpenny per word, will be the charge for telegrams to Austria. Local messages will be charged half a kreuzer, or the tenth part of a penny, per word.

Portsmouth.—The Portsmouth and South Hants Electric Supply Company, which has already applied for Parliamentary powers, has given the contract for the erection of the central station to the House-to-House Company. The station will be a duplicate of the one which that company has in operation at West Brompton. A large number of hotel-keepers and tradespeople in Portsmouth are giving the scheme their support. The Portsmouth Town Hall is being fitted with electric light appliances by Messrs. Haden and Son, of Manchester.

Sale by Auction.—We have received from Messrs. Wheatley, Kirk, Price and Goulty a carefully-printed catalogue of the fixed and loose plant, and machinery, &c., to be sold by auction by them on Tuesday, Wednesday, Thursday and Friday next, at the works

Digitized by Google

of Messrs. Appleby Brothers, Limited (in liquidation), at East Greenwich. The sale includes a large quantity of high-class engines, boilers, tool-cutting machines, shafting, pulleys, &c. Further particulars will be found in our advertising columns.

Submarine Cable Tender.—The Direction-Générale des Postes et Telegraphes invites sealed tenders for the material of a submarine cable: (1) Galvanized iron wire 2·5 millimetres in diameter (2 lots); (2) tarred jute strips (1 lot); (3) submarine cable core (2 lots). The conditions of tender may be inspected at 103, Rue de Grenelle, Paris, any day (except holidays) between the hours of 11 and 4, and also at the chief telegraph offices. The tenders will be opened on the 22nd of this month.

Price List of the "Sunbeam" Lamp Company.—The "Sunbeam" Lamp Company are now manufacturing incandescent lamps from 200 up to 1,500 candle-power. They are made in two classes, A, high efficiency, B, longer duration, the former taking only two watts, and the latter two and a-half watts per candle. The "Sunbeam" lamp is likely to prove very useful for certain kinds of street lighting and has already been extensively employed on board ship and in the lighting of large halls. The prices charged are very moderate.

A New Spray Arrester.—The fumes arising from batteries are at times found extremely troublesome, and different methods are in use for their prevention. Messrs. Drake and Gorham have recently introduced a special preparation of light material, which is floated on the acid. Every crevice is effectually covered, and it is found that secondary batteries, even when overcharged to any extent, cause no nuisance when thus protected. The cost is stated to be very trifling—in fact, considerably less than the glass plates which are usually employed.

Electric Traction on the North Metropolitan Tramway.—On Tuesday last week the last of the five accumulator cars of the Electric Traction Company was put on the North Metropolitan Tramway at Canning Town, and the whole of that line is now worked by electricity. For some weeks past the cars have been added one by one to work among the horse cars, and 15,000 car miles have now been run upon this line by the accumulator cars with only a loss for stoppages of 2 per cent. of the total possible mileage. The cars carry a complement of 52 passengers.

Strand Union.—Tenders have been received for electrically lighting the Board room and offices of this union from the following firms:—

Messrs. Rashleigh Phipps and Dawson, Berners-street ...	£88 0*
Messrs. Hart, Son, Peard and Co.	98 15
Messrs. Vaughan and Brown, Kirby-street	86 0
Messrs. Verity and Sons	81 7

* With £18 extras.

The tenders were referred to the General Purposes Committee for consideration.

Telegraphic Cables in the Philippines.—A few months ago we announced that an invitation for the construction of inter-insular cables in the Philippine Archipelago had been withdrawn owing to no tender having been sent in. Tenders were again invited, and advices from Madrid report that the Committee appointed to take charge of the matter met last week under the presidency of the Colonial Minister, and reported that one tender had been submitted, viz., by Mr. Clavet, in the name of the Eastern Extension, Australasia, and China Telegraph Company (Limited). The Committee decided to consider the proposal, and report at an early date.

Edinburgh Electrical Exhibition, 1890.—The Committee under whose management the electrical branch of the Exhibition will be placed has now been constituted as follows:—A. R. Bennett, General Manager, National Telephone Company; Principal Grant Ogilvie, Heriot-Watt College; Prof. G. F. Armstrong, Edinburgh University; J. Gibson, Superintending Engineer, Postal Telegraphs; A. F. Clement, Telegraph Superintendent, North British Railway; Dr. A. C. Elliott, Edinburgh University; D. A. Stevenson, Engineer to Commissioners of Northern Lights; Colonel Malcolm, Royal Engineers; J. Monteith, Carstairs House; G. Auldjo Jamieson and Hugh Auld, the three last being gentlemen locally identified with the progress of electrical science.

City and Guilds of London Central Institution.—At the termination of last session the John Samuel Scholarship was gained by A. E. Young, and the Siemens Medal for the student of greatest merit in the department of electrical engineering by C. G. Lamb. At the entrance examination for the new session held this month the Clothworkers' Scholarship of £60 a year, tenable for two years and renewable for a third year, entitling the successful candidate, in addition, to free education, was gained by H. C. Haycraft; the Mitchell Scholarship of £30 a year for two years, with free education, by F. H. Hummell; the three Institute's Scholarships, of sufficient value to cover the student's fees, each tenable for three years, by R. W. Weekes, H. E. J. Taylor and E. G. Ingold; and the Public School Scholarships, entitling the successful candidate to free education, by R. L. Jenks and C. Mills.

Obituary.—We regret to have to announce the decease of the head of the old-established firm of Hick, Hargreaves and Co., proprietors of the Soho Ironworks, Bolton. Mr. William Hargreaves died at his residence, Moss Bank, Halliwell, near Bolton, on the 1st inst. The deceased gentleman was in his 68th year, and had been in failing health for a considerable period. Mr. Hargreaves has been head of the firm since 1868. It may be of interest to note that this firm was the first to introduce the Corliss engine into this country. Messrs. Hick, Hargreaves and Co. have also achieved considerable celebrity in the development of massive hydraulic and electric lighting machinery and plant, one of their latest works in this direction being the construction of two pairs of engines of 3,000 horse-power and two other pairs of engines of 10,000 horse-power for the London Electric Supply Corporation.

London County Council.—The Highways Committee of the County Council reported last week that it had assented to the House-to-House Electric Light Supply Company laying mains for the supply of electricity in Kensington. The Council expressed its disapproval of the works referred to in the notices issued by the Kensington and Knightsbridge Electric Lighting Company, on account of the largeness of the distributing boxes which the company proposes to adopt. The Council gave its sanction to the notices issued by the London Electric Supply Corporation; the notice referring to the works to be commenced at once by the Metropolitan Electric Supply Company; the works specified in the notice of the Chelsea Electricity Supply Company, providing that the covers of the distributing and other boxes consisted of iron frames filled in with stone or other material to suit the paving; and the laying of the St. James's and Pall Mall Electric Light Company's mains, upon condition that the work was carried out to the satisfaction of the proper authorities.

An Electrical Trades Union.—A meeting of electric engineers and linesmen, of whom it is estimated there are about 3,000 in London, was held last Saturday at the Paul's Head, Paul-street, Finsbury, to discuss a proposal as to the means for the formation of a society in London on the Trades Union principle. The workman who was elected to the chair wished his name—as did also the speakers who followed—to be suppressed, in view of future reprisals from the firm by which they were employed. In opening the proceedings the chairman said he was very much surprised that such a Union as was then under consideration had not been formed before. As a matter of fact, their leaders had been responsible for the delay, but now that they had commenced in earnest they could see plenty of useful work before them. Throughout the trade wages were far too small, considering the dangers they had to incur; for when they started out in the morning there was not one of them who could say with any certainty whether he would be alive in the evening. He did not believe in strikes, but he did believe that when their Union was duly established on a sounder basis it would do valuable work in the way of calling in an independent arbitrator in the event of a trade dispute ultimately taking place. Mr. Donald, Labour Union, urged organisation, so that labour might reap the benefit of the wealth it created. A hearty vote of thanks having been accorded to Mr. Donald for his speech, a letter was read from the Manchester Union urging the London men to amalgamate, and it was decided that the Union should be formed.

THE PRACTICAL UNIT OF INDUCTION.

BY W. E. AYRTON.

On page 454 of *The Electrician* for September 6th, which I have just seen on my return to town, I find the following in the report of the recent Paris Electrical Congress :—

"The results of this discussion, as embodied in the votes of the Section, were as follows :—

"1. The name 'quadrant' was adopted for the unit coefficient of induction. This is equal to 10^9 C.-G.-S. units, and is the same as the secohm of Messrs. Ayrton and Perry."

I have also heard during the last few days that this name "quadrant" was subsequently adopted by the Electrical Standards Committee of the British Association at their meeting at Newcastle, last month.

Permit me, at this somewhat late period, to point out that 10^9 C.-G.-S. units is neither the practical unit of induction nor is it "the secohm of Messrs. Ayrton and Perry." For the practical unit of induction, whatever name you like to give it, is that unit which when used to measure L in the following equation—

$$r\,C + L\,\frac{dC}{dt} = E,$$

makes that equation true, where r is the resistance of the circuit measured in the so-called legal ohms, C the current measured in amperes, and E the E.M.F. measured in *practical* volts. Now, without waiting to express my opinion on the question which I understand occupied the attention of the British Association Committee, viz., whether an induction is really a length, or is only numerically represented by the measure of a length, it is quite certain that the *practical* unit of length in the preceding inductional equation is not 10^9 centimetres, and therefore that the *practical* unit of self-induction cannot be that length.

Although the legal ohm is perfectly defined as the resistance of 106 centimetres of mercury, one square millimetre in section at 0°C., the *exact* velocity which corresponds with the legal ohm is not yet known. It is certainly not 10^9 centimetres per second, and is probably about 99777×10^4 centimetres per second. If, then, we desire to define the *practical* unit of induction as a length, we certainly cannot say that it is 10^9 centimetres, since the practical unit of induction must satisfy the practical inductional equation given above. We might logically say that the practical unit of induction was "*probably about* 99777×10^4 *centimetres*," but such a statement would not constitute a scientific definition. In fact it will be impossible to state the exact length that corresponds with the present practical unit of induction until the exact velocity corresponding with the legal ohm is known.

A few years ago, when the B. A. unit of resistance was the recognised ohm, the practical electro-magnetic unit of length was *about* 98668×10^4 centimetres; to-day it is *about* 99777×10^4 centimetres, and if the accuracy of experimenting can be immensely increased, and national jealousy entirely overcome, some of us may live to see this practical unit of length reach the scientific goal of 10^9 centimetres by successive stages of Darwinian process. But as long as that unit of length is not accurately known, and as long as the difference between it and 10^9 centimetres is probably over 2 in 1,000—a difference that it is easy to measure electrically—it appears to me now, as it appeared to Prof. Perry and myself nearly three years ago, that the proper definition of the practical unit of induction should not be based on any approximate length (still less on the exact length of 10^9 centimetres, which is certainly not the measure of the practical unit of induction). On the other hand, just as the legal volt is defined in terms of the legal ohm and ampere, to make the equation

$$r\,C = E$$

true for steady currents, so it appeared to us that the practical unit of induction should be defined in terms of the ohm and the second, so that the equation

$$r\,C + L\frac{dC}{dt} = E$$

might be true for ohms, amperes, units of induction, seconds, and volts.

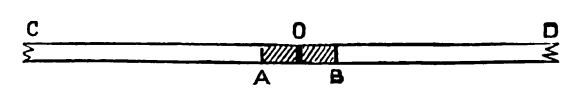
Whether the name "secohm," which we then suggested as a contraction of second and ohm, was a happy one is for others to judge, but I feel as sure now as I did then that the idea underlying that name is correct. With a box of accurately adjusted legal ohms and a good watch, one can, *without the use of any other standards*, measure the self-induction of a coil in secohms theoretically to any degree of accuracy desirable, a result not theoretically possible if the result has to be stated in "quadrants." On the other hand, if the self-induction of a coil be accurately known in quadrants, then, since the resistance of a circuit can only to-day be expressed with *theoretical* accuracy in legal ohms if the result is to have *international* consent, it is impossible to use the inductional equation to measure with theoretical accuracy the growth of the current in the circuit in amperes.

Now, although for practical purposes the error of a few tenths per cent. in a measurement is often of no consequence, it appears to me that as the ideas of induction are only now being grasped by practical men, it is of the utmost importance that the definition of the *practical* unit of induction should be rigorously exact. I am also extremely doubtful whether any practical electrician's conceptions of self and mutual induction would in the slightest degree be extended by the practical unit being defined as a length (even if it were possible to exactly state that length); and I am quite certain that such a definition would give him no assistance whatever in measuring with a metre scale the self-induction of even an ideally simply constructed coil, still less of any coil that he is likely to have to deal with. Self-inductions will, I fancy, continue to be measured for some time to come by practical men as they have been measured during the last year or two, and as long as the present legal ohm is the standard of resistance, self-induction will be expressed in a unit which has had no name given to it by the Paris Congress or by the British Association, and the value of which cannot yet be exactly stated with international consent in terms of a length, and therefore cannot be exactly stated in terms of the adopted unit, the "quadrant."

THE ELECTROMOTIVE FORCES PRODUCED BY THE CONTACT OF SIMILAR METALS AT DIFFERENT TEMPERATURES.

BY HERBERT TOMLINSON, F.R.S.

Both Prof. O. Lodge and Mr. Shelford Bidwell in commenting (*The Electrician*, October 4, p. 546) on Prof. H. Stroud's Paper, "The E.M.F. Produced by an Abrupt Variation of Temperature at the Point of Contact of Two Portions of the same Metal," do not agree with Prof. Stroud in his interpretation of the results obtained by him. The present writer is inclined to believe with Prof. Lodge and Mr. Bidwell that the results obtained by Prof. Stroud are not due to the electromotive force of the Thomson effect, and would suggest the following as a possible explanation :—



Suppose that C D is a tube of copper of exactly the same structure throughout, and that we strike it with a hammer at O. The effect of the blow will be to modify the molecular structure of the tube for some little distance on either side of O; let A B be the portion of the tube thus modified. Now let us keep the portion of the tube at A warmer than the portion at B, then an E.M.F. will be developed in the direction A B. When Prof. Stroud cuts his tube, the act of so doing permanently modifies, by mechanical means, the molecular structure of the portions at and adjacent to the cut, and the modification, of course, persists after the cut surfaces have again been brought into contact

Digitized by Google

with each other; the tube C D is no longer of the same structure throughout. As a consequence of this, when opposite sides of the cut are maintained at different temperatures, we obtain Prof. Stroud's E.M.F., which is in a direction indicating that the act of cutting the tube alters the thermo-electric power of copper in the same direction as the act of hammering. If for copper we substitute iron, the E.M.F. should be reversed in direction, as Prof. Stroud finds, for the thermo-electric powers of copper and iron are affected oppositely by the same mechanical processes. If the above view of the matter be correct, Prof. Stroud's observed E.M.F. should be lessened* or entirely destroyed by *annealing* the pieces *after cutting*.

Prof. Magnus has fully investigated the currents produced on causing hot and cold wires to touch each other, and a concise account of his work will be found in Tyndall's "Researches on Diamagnetism and Magne-Crystallic Action," p. 296. It will, perhaps, be not out of place to compare in the following table some of the results of Prof. Magnus with those of Mr. Bidwell:—

Contact current hot to cold = +. Cold to hot = −.

Metals.	Magnus. One wire 100° C., the other 8° C.	Magnus. One wire 250° C., the other 8° C.	Bidwell.	Thomson effect.
Iron	.....	.....	−	−
Platinum	+22	+80	+	−
German Silver	−72	.....	+	−
Cadmium	+15	.....	+	+
Zinc	+28	.....	+	+
Silver	− 3	−17	−	+
*Gold	+ 6	+28	−	+
Copper	− 8	.....	−	+
Lead	0	.....	0	0
Tin	−10	.....	+	+
Nickel	.....	.....	+	−
Palladium	.....	.....	−	−

* The gold of Prof. Magnus was alloyed with 2·08 per cent. silver.

The numbers in the second and third columns of the table are the degrees of temporary deflection of the galvanometer needles produced by suddenly bringing the hot wire into contact with the cold one, and will, therefore, for the most part represent approximately the relative values of the resulting electromotive forces. It will be observed that the direction of the E.M.F. in the lists of metals furnished by Prof. Magnus and Mr. Bidwell is not in all cases the same. This may arise partly from the fact that the metals were not of the same degree of purity in the two cases. The writer many years ago made experiments on the same subject. His results agree with those of Mr. Bidwell as regards the direction of the E.M.F. in iron, German silver, platinum, lead, silver, nickel, zinc, and pure copper. The one specimen of commercial copper examined by him gave a + sign, but another specimen examined recently, and probably of better quality, was −. With a specimen of nearly pure tin a − sign was found. These conflicting results, obtained by different experimenters, plainly show us that we must be on our guard as to drawing conclusions respecting any relations which there may or may not be between the Thomson effect and the thermo-electric currents produced by the sudden contact of hot and cold wires. The two things ought to be determined not with different specimens of the so-called same metal, but with the self-same specimens.

In connection with the matter in hand it may perhaps be of interest to the readers of *The Electrician* to learn that a temporary E.M.F. can be developed by suddenly putting two wires of the same metal, one hot and the other cold, into a liquid. In most cases the direction of the E.M.F. seems to be the same at all temperatures of the hot metal where ordinary water is the liquid employed, but in the case of copper it is not so. When either pure or commercial copper wire is heated to a temperature under 100° C., it becomes positive with respect to copper at 15° C. when the two wires are simultaneously put into water at 15° C.; and when it is heated above 100° C. it becomes negative. An easy way of showing this is to connect two pieces of copper wire with a galvanometer of many turns; heat one of the free ends in a glass tube to a temperature of 300° or 400° C., and then simultaneously place the two ends about ½in. apart on a piece of wet paper. If the galvanometer be at all sensitive there will be at first a strong deflection, showing a current from cold to hot copper through the wet paper; this deflection will rapidly subside, and then a deflection in the opposite direction ensues. If ammonium sulphide be used instead of water, the hot copper is negative to cold copper—at any rate up to about 300° C., and probably beyond, though this was not tried.

* It is often very difficult to *entirely* annul by annealing the effects of mechanical processes.

REVIEWS.

Incandescent Wiring Handbook. By F. B. Badt. (Electrician Publishing Company, Chicago, 1889.)

This is a useful little book of American origin, and containing in its sixty-five pages a great deal of practical information on a subject about which very little has ever yet appeared in print. It is a book which, with some corrections adapted to English ideas, and which we shall note below, might usefully be placed in the hands of every foreman engaged in house-wiring. The author displays sound, common sense in going straight at the practical details, omitting any unnecessary preliminaries under the pretence of imparting scientific information. Chapters I. and II. each consist of less than half a page of print, and describe respectively the ordinary parallel (here called "multiple-arc") and the three-wire system, just so far as a wirer needs to understand them. The diagrams are good. Chapters follow on cleats, mouldings, and concealed-work, and some practical hints are given as to fishing for wires under floors or behind partitions in a completed building. The author very properly insists that in new buildings the architect should make ample provision for electric lighting wherever there is any probability of its coming into use. This can be done at a trifling additional cost whilst the erection of the building is proceeding, and may save a good deal of expense, to say nothing of inconvenience at a later date. Even if no more is done, it will often save much tiresome labour if in each room of the house one of the spaces running between the joists under the floor is kept clear of obstruction, or if a passage-way is cut in such as are inevitable. A small draw-wire should be laid in each such channel, and they should be made continuous from room to room upon the same floor. Vertical channels in corresponding positions should be cut in the brick-work of the walls. A still better plan—which the author does not mention, although it has come into use both here and in America—is to provide suitably arranged tubing throughout the premises, into which the wires can at any time be drawn. This system was strongly commended at the recent meeting of the Edison Illuminating Companies at Niagara Falls.

But, undoubtedly, whenever practicable, the most satisfactory way is to complete the wiring whilst the house is being built. The best time for doing the work is "when the builders have finished boarding in, and have not yet begun lathing." The author estimates that at this time the cost of wiring is sometimes not more than half as much as in the finished structure. But this remark will scarcely apply over here, where labour does not bear so high a proportion to the total cost.

Mr. Badt has not very much to say on the "location" of switches and cut-outs, nor can very much be said; this is a detail which must be settled by a responsible person in reference to the circumstances of the case.

In America, however, they are more partial than we are here to the system of bringing together as many switches and cut-outs as possible at one point. Mr. Badt lays it down that "it is not necessary that each room should have its own switch," and he votes in favour of double-pole switches on the ground chiefly of convenience of testing, He might have added that they have also a tendency to provide occupation for the tester. For soldering he prefers acid on the ground that the workmen will make a better job than with resin. This is a point upon

Digitized by Google

which practice is very varied, but there is little doubt that when the job is in the hands of first-class workmen (where alone it ought always to be), resin is the right flux. Mr. Badt, by implication, allows unsoldered joints; there is a sentence on page 21 which should therefore be erased before the book is placed in the hands of an English foreman. In fact, in the matter of joints, all our best contractors can "give points" to the Yankee. Unhappily, there is still so much work being done by more or less incompetent people, and these may learn something even from American practice in this particular.

Safety rules we pass by, as we have our own versions to strive to live up to. The chapter on "Insulation and Testing" is mainly the reprint of a passage taken from a Paper by "Prof." J. D. F. Andrews (see *Electrician*, April 5, 1889, p. 619). (We may remark in passing, that in such honour do American writers hold the English school that every year the honorary degree or title of Professor is conferred by them upon a number of our esteemed countrymen. Prof. Reckenzaun holds, we believe, the premier distinction, but we have also Professors Rankin Kennedy, Esson, Mordey, and Swinburne, all holding American degrees; and now we have to congratulate a respected Glasgow contractor on his attainment of the same high distinction. May we venture without impropriety to suggest that some surprise has already been expressed that the claims of Mr. Killingworth Hedges have been so long overlooked?)

Returning from this digression we note that the author very properly urges the necessity for paying attention to the insulation of every wire as it is put in. Probably a more extended use of the magneto-bell in the hands of properly-instructed foremen would often save a lot of subsequent trouble.

There is a useful chapter on the wiring of fixtures and lifts, and one on wire gauges; and then we come to some "General Electrical Data," which has at least the merit of brevity.

The last twenty pages are on calculating the size of wires. Six "Rules" are given for this purpose, which will be useful to such people as do not readily grasp the purport of a simple algebraic formula; those who do won't bother themselves much about "rules." In the examples with which the application of the rules are illustrated Mr. Badt usually takes the fall of potential in the wires at 10 per cent.! Not only is this a quite impossible figure in house-wiring, but for short lengths it is very likely to suggest to the too-trustful disciple a wire which, with the proposed current, is certain to overheat. We are indebted to Mr. Badt for the information that "the National Board of Fire Underwriters specifies that the carrying capacity of a conductor is safe when the wire will conduct a certain current without becoming painfully warm when grasped by the closed hand." *Whose* hand is not specified, but before the law can become of general application it is clear that we shall want a definition of the standard hand as regards its capacity for standing "fire." All through this chapter on "Safe Carrying Capacity" we find we don't like the author *quite* as well as we did before. We do not dispute that "in nature nothing is lost," but we did not expect that Mr. Badt would remind us of it.

Lastly we come to an ingenious table (contained in a separate pocket in the cover) which enables one to find the size of wire required for a given number of lamps of given voltage at a given distance, with any fall of potential from 1 per cent. to 15 per cent. There are three distinct tables, for 55, 75, and 110 volts respectively. The size of the wire is found in circular mills, and in Brown and Sharp's gauge.

On the whole, it is impossible to resist the conclusion that American ideas in this matter are scarcely on a par with our own. The very fact that a wiring table is calculated for various falls of potential, from 1 to 15 volts, would seem to show that more attention is paid to what is, after all, a small saving in the cost of copper than to safety and efficiency. In this country, although no doubt plenty of bad work is still being done, it would nevertheless be difficult to find many installations with a drop of 5 to 10 per cent., such as Mr. Badt chooses to "figure on" (to use the elegant native expression). Amongst the best firms in this country the custom in house-wiring is to calculate the more important mains and branches for a fall of 1 per cent., and then to instruct the foreman that the current density in the remaining leads is in no case to exceed a fixed quantity, say 500 or 700 amperes per square inch. The foreman is not then required to find out anything further than the number of lamps which the wire will have to carry, and at the same time safety and efficiency are practically assured. This is well worth the slight extra cost which may be incurred.

Electricity in our Homes and Workshops: A Practical Treatise on Auxiliary Electrical Apparatus. By SIDNEY F. WALKER, M.I.E.E., &c. (London: Whittaker and Co.; George Bell and Sons, 1889.)

If the author had seen fit to dispense with the first part of the above title, the remaining half would have given by itself a better idea of its style and contents, and we should think the excision would have materially assisted the volume to reach the class for whom it is intended—and to whom, we may at once add, it should prove very serviceable. It would be difficult to find a more painstaking writer than Mr. Sidney Walker when he is describing the conditions of practical success in a field which he has himself thoroughly explored. The chapter on Electric Mining Signals is itself a mine of apparently exhaustive detail on the subject of which it treats. Nor is it for a moment to be supposed that the subject is either a simple or an unimportant one. To design and maintain economically a set of electric bell signals under the conditions of damp and exposure to rough usage which are found in a coal mine presents a problem of which nothing but skill and foresight, but above all experience, can furnish the complete solution. Mr. Walker's book will now enable all who are practically concerned in the business to participate in the lessons which experience—often evidently of a costly and painful character—has imparted to him. The author does not confine himself merely to suggestions as to the design of the installation; he considers in much detail the character of the faults likely to arise at the various points, and how they may be most quickly traced and best remedied. The sections which relate to the method of procedure in testing for a leakage or a disconnection, which cannot readily be found, should be the means of saving an immense amount of time and trouble to persons inexperienced in the work. One is not surprised to learn that the vertical wires descending the shaft are chiefly liable to injury, and most difficult to repair. The author prefers to use one covered copper and one bare iron wire in this situation; he gives reasons for this at length, but we must refer readers who wish to study the question to the book itself.

The leading principle on which the author again and again insists is that for economical work in any description of electric bell-hanging you must have large cells. Pint cells, he would probably say, may sometimes be good enough, but quart cells are always better, and the half-gallon size is invariably best of all. This, of course, refers to cells of the Leclanché type. The author estimates that the annual cost of maintenance varies inversely as the size of the cell.

Besides the chapter on Mining Signals we have chapters on Electric Bells, Batteries, and Telephones, all of which are practical and useful.

Of the remainder of the work (which is, in fact, the three first chapters) we cannot speak so favourably. For the "young electrical engineers who are just commencing to make their practical experience," for whom the preface says the book is meant, the chapter on elementary principles should be wholly unnecessary. The chapter on "The Electric Current" and the one on Magnetism contain some good points, but they are occasionally marred by a looseness of statement which should not have been allowed to pass. It is neither an wholesome nor even a truthful doctrine to say that "Carbon, like every other known body, is soluble by the current." The author deals strangely with the term "magnetic circuit;" he speaks of "breaking" and "making" it as if it were the exact analogue of the electric circuit. We may properly speak of "opening" or "closing" a magnetic circuit, but we certainly can neither break nor make it. We are told that "when a permanent steel magnet is brought near a piece of iron or steel, magnetism is induced in it *provided* it lies in the path of the magnetic circuit." The only "proviso" really required is that the perma-

Digitized by Google

nent magnet shall not take the shape of a closed ring; otherwise the iron will surely lie "in the path of the magnetic circuit."

Lastly, we are bound to call attention to the one serious practical error which we have noted, and which will be found on page 40. Mr. Walker there and on earlier pages warns the student that Ohm's law must be rigorously applied to insulators, but he has not a word to say about the far more important point of surface leakage.

A NEW ALTERNATING-CURRENT MOTOR.*

BY LIEUT. F. JARVIS PATTEN.

On giving our secretary the title of this Paper it was my purpose to treat the subject in a broader light, and to show the progressive steps in a series of experiments which led eventually to the type of machine that I shall bring to your notice this evening. The recent and urgent claims of other work have rendered such a treatment impossible at the present time, and I shall limit the Paper to a description of a new alternating-current motor, one form of which is shown in the accompanying drawings.

The place that the alternating-current electric motor is destined to fill in the industrial arts is familiar to you all, and the various ways known to the scientific world by which such machines may be rendered operative have been ably considered and elaborately discussed in the Institute Papers of the past two years by Professor Thomson, Dr. Duncan, and Mr. Tesla; we are thus all more or less acquainted with the prominent difficulties of the problem.

My experience, in common with that of my predecessors, teaches that the alternating-current motor has a strong and persistent disposition to stand still, and when persuaded to motion it is apt to be a sort of "go-as-you-please" machine, and asserts its inherent right to turn in either direction indifferently; direction of rotation in some cases being purely a matter of chance. I shall not have much to say about efficiency, as my experiments with large machines are not sufficiently advanced to furnish any reliable data, but I will endeavour to give a general solution of the problem designed to meet the following conditions of practice:—

1. A machine that will start itself independently of the speed of the generator or number of alternations of current per unit of time.

2. A machine that has but one direction of rotation and cannot reverse under any conditions of current alternation.

3. A machine that is not necessarily synchronous with the generator, revolution for revolution.

4. A machine in which reversals of current direction do not produce corresponding reversals of magnetism in any iron part, when the machine is in motion at its normal speed and maximum efficiency.

5. A machine of simple form, having an ordinary continuous-wound armature revolving in a single or two-pole field.

Referring now to the figures which are simply diagrams of the circuits and operative parts, we have in Fig. 1 an ordinary closed circuit armature shown as a Gramme ring merely for convenience of illustration, the points of the winding intermediate between the eight coils being connected in the usual way to the eight segments of bars of an ordinary Gramme collector, and it may be well in passing to note here the function of this collector. It is not a commutator in the strict sense of that term, as it does not rectify or re-direct reverse or opposed currents. If the brushes b^1 and b^2 were held upon the outside wire of the ring the same results would follow, and the Gramme collector, properly so called, singly transfers the brush contact from point to point of the continuous ring winding. If a source of direct current be interposed between the terminals A^1 and A^2 current will flow continuously from brush b^1 to brush b^2 downward through the right and left-hand halves of the ring in the direction of the arrows k^1 and k^2, making, say, a south pole in the ring at the upper point S, and a north pole at the lower point n. With a continuous current these poles would be continuously maintained and placed in the magnetic field indicated by N and S; the armature would continuously revolve in the direction indicated by the arrows re. If now a source of alternating current be inserted between the terminals A^1 and A^2 the polarities of the ring would be reversed at each successive alternation of current, and if a direct impulse, indicated by the single arrows in the external circuit, produced the poles n and s in the ring, the reverse impulse indicated by the double arrows would produce the opposite polarities n^1 and s^1 at the same points, and the tendency to motion would be reversed if the fields remained the same, but it will be noted the motion would be in the same direction still if the fields also were reversed by the same reversal of current. If, however, the fields were maintained constant, as indicated by the large letters N and S, and some device could be contrived by which at each reversal of the alternating current the brushes b^1 and b^2 could be made to change position, either mechanically or otherwise, then with an alternating current a constant polarity, s and n, would be maintained at the upper and lower points of the ring—for then a direct impulse starting from A^2 to the right would enter the ring through the brush b^1 flowing down both sides in the direction of the arrows k^1 k^2, out through brush b^2 and back to the source at A^1. The reverse impulse indicated by the double arrows would start from A_1 to the left, going to brush b^2, and if we now suppose this to have changed places with the brush b^1 the reverse current would then enter the ring at s and flowing down both sides in the direction of the arrows k^1 and k^2 would leave through n and the brush b^1 and so back to the source A^2, maintaining the polarity of the ring the same as before. If the brushes could be thus changed at each alternation, the polarity of the ring would be maintained constant with an alternating current. While, however, it is quite impractical to thus cause the brushes to change position mechanically at each reversal of current, it is perfectly feasible to produce the same effect without the mechanical change. The means of accomplishing this result are indicated in Fig. 2, which is identical with Fig. 1 with a single exception. There are eight coils as before, and eight bars in the collector, the odd-numbered bars, 1, 3, 5, and 7, being connected to the same points of the ring as before, c, f, h, and j, but the even-numbered bars, 2, 4, 6, 8, are connected respectively to points of the ring diametrically opposite them, bar 2 to the point d, bar 4 to the point g, and so on, each even-numbered bar to a corresponding opposite point of the winding. If now a source of alternating current be interposed between the terminals A^1 and A^2, and we make the single supposition that the ring shall turn through an arc of the circumference equal to that covered by one bar of the collector during each alternation of current, we shall still maintain a constant polarity at the upper and lower points of the ring without causing the brushes to change position mechanically.

Thus a positive impulse starting from A^1 to the left, and indicated by single arrows, enters the ring at b^1, flows down both sides to n, producing the ring polarities s and n, out at brush b^2 and back to source at A^2. The reverse impulse being in the opposite direction will start from A^2 to the right, go to brush b^2, which we will now suppose bearing on segment 4 of the collector, whence it will go by the inverse connection to the opposite point s^1 of the ring, then down both sides in the same direction as before to the point n^1,

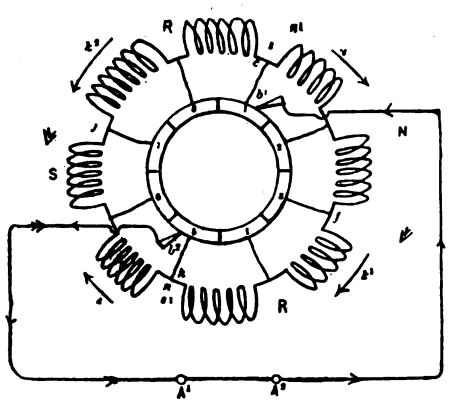


Fig. 1.

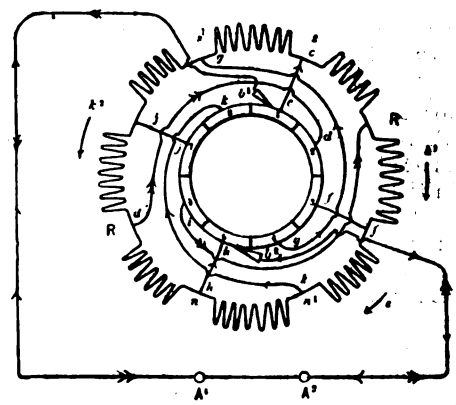

Fig. 2.

* Paper read before the American Institute of Electrical Engineers, New York, September 10, 1889.

Digitized by Google

thence back to the opposite segment 8, out at brush b^1 now bearing on this segment, and back to source at A^1.

The reverse currents, therefore, under the assumed conditions, are caused to maintain a constant polarity in the ring, so that in a constant field its tendency to motion would always be in the same direction with an alternating current in the armature. It will be further noted that the alternating current is not re-directed or commuted in the strict sense of the word, and we may enunciate the fundamental principle which underlies the construction of this type of machine as follows :—

"*The poles of any closed circuit may be maintained constant with an alternating current by causing opposite impulses to traverse the circuit in opposite directions.*" The direct and inverse connections shown in Fig. 2 have precisely this effect, when, as supposed, a

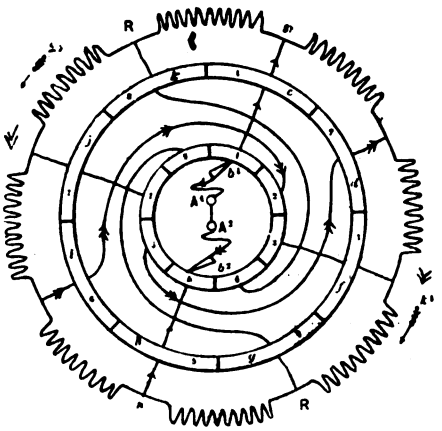

Fig. 3.

single bar of the collector passes under the brushes at each reversal of current. The connections *c c*, *d d*, *f f*, &c., in Fig. 2 may have any form, and other bars may be interposed between their extremities without affecting in any way their functions as connectors. This step is shown in Fig. 3, where another collector bar 1*c*, 2*d*, 3*f*, &c., is inserted in each of the connections *c c*, *d d*, &c., of Fig. 3, thus making another collector, shown outside the first to avoid confusion of the drawing, while for the same reason, the source of alternating current A^1 A^2 is placed inside the inner ring. As the polarities *s* and *n* of the ring are maintained constant as previously described with an alternating current, and current is constant in direction from *s* downward through the right and left halves of the ring to *n*, so must necessarily any current be constant in direction which is led from brushes through any shunt circuit connected to the segments 1*c* and 5*h* of the outer collector ; a field circuit of constant direction may therefore be shunted from this outside

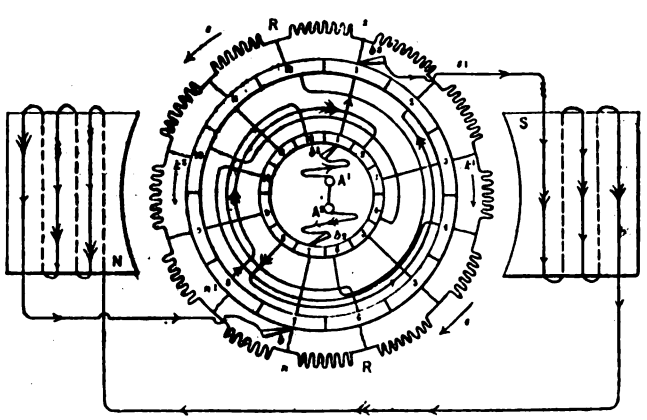

Fig. 4

collector. This is shown in Fig. 4, in which twelve coils are shown in the ring and twelve bars in each collector connected alternately direct and inverse as before. Tracing now two opposite impulses of current, we have the first indicated by the single arrows from source A^1 to segment 1 of the inner collector, thence to segment 1 of outer collector, where the current divides, part going down the right and left-hand halves of the ring to *n*, and part out brush at b^3 through the field circuit, making the poles N and S back to brush b^4 segment 7 of outer and segment 7 of inner collector to the terminal A^2 of source. If the armature be supposed now to turn through the space covered by one collector bar, the reverse impulse can be traced as follows :—Starting at A^2 in the opposite direction to brush b^2 now bearing on segment 8 of the inner collector, thence through the reverse connection to segment 2 of the outer collector, now under brush b^3 where the current divides, going part as before down the right and left halves of the ring, making a south pole at s^1 and a north pole at n^1 as before, and the other part out of the brush b^3 through the field-circuit in the same direction as before back to brush b^4 now on segment 8 of the outer ring, thence through the reverse connection back to segment 2 of the inner ring, now in bearing with brush b^1 and so returning to the source at A^1. Thus the two impulses of opposite direction have been made to traverse both armature and field-circuits in the same direction. We have therefore with an alternating current constant armature polarity, and constant field-polarity, and therefore a constant tendency to motion in the same direction. Not only this, but the further condition is fulfilled that there are no reversals of magnetism in any iron part so long as one bar in the machine, as shown in Fig. 4, passes under the brushes at each alternation of current. It remains to show how this is brought about. Referring again to Fig. 4, let it be supposed that the first impulse of current did not cause the armature to turn through the arc of the circumference subtended by one segment, but all the brushes still bore on the same segments as shown in the figure and the reversals of current continued—by tracing the circuits it will be seen that each reversal of current reverses the polarity of both field and armature, and with either direction of current or rapid reversals, there will be a constant tendency to motion always exerted in the same direction. The machine under these conditions becomes therefore simply a direct-current machine on an alternating-current circuit with a constant tendency to start in one direction. Assuming the machine therefore self-starting, it will continually gain in speed until the condition is fulfilled of one segment passing the brushes at each alternation, for it then becomes in the broad sense a synchronous

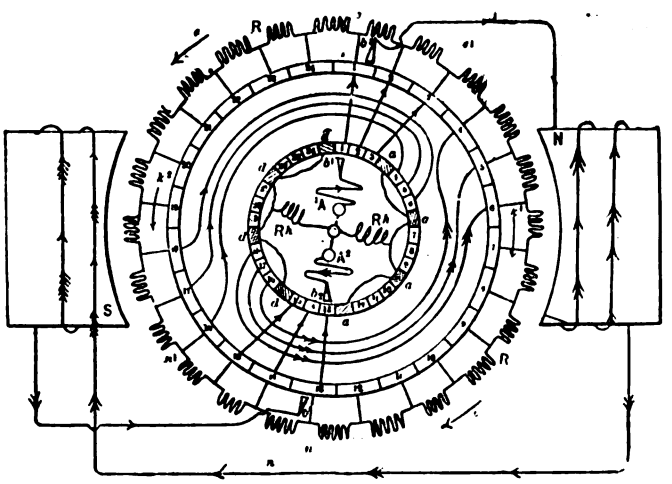

Fig. 5.

alternating motor. The current then produces no reversals of magnetism and there is a true alternating current in the armature circuit—producing however no reversal of armature polarity—and a current of constant direction in the field. Under these conditions the motor is self-regulating, moving at a constant speed and with a maximum rotary effort.

It is not, however, essential that one bar should pass the brush at each alternation, as any number may be caused to do this, depending upon the speed required and the number of coils upon the armature. This is illustrated in Fig. 5, where the complete machine is shown. There are twenty-four coils in the armature, twenty-four bars in the outside collector, and thirty-two bars in the inside one, this latter being composed of twenty-four connecting and eight insulating bars. The connecting bars of the inner ring are numbered to correspond with those of the outer ring around to the right, from one to twenty-four ; the insulating bars, drawn shaded, separate the others into groups of three. In this machine three segments, 1, 2, 3, in the outer ring are connected direct to the corresponding segments, 1, 2, 3, of the inner ring ; likewise the opposite three, 13, 14, 15, of one ring are connected direct to 13, 14, 15 of the other. The next group of three is connected inversely, 4, 5, 6 of the outer ring to the diametrically opposite bars 16, 17, and 18 of the inner ring, and the corresponding opposite group 16, 17, 18 of the outer ring are likewise connected inversely to the diametrically opposite group 4, 5, and 6 of the inner ring. The remaining segments are connected in the same manner, but the connections are omitted to avoid confusion of the drawing. The operation of the machine is evidently the same as that shown in Fig. 4, except that the required conditions are fulfilled in this instance when three bars of the collector pass

Digitized by Google

under the ring at each alternation of current; and as there are 24 segments arranged in groups of three, the machine at its normal speed would make one revolution for every eight alternations of current, and connected in a circuit supplied with 16,000 reversals per minute, its normal speed would be $\frac{16000}{8} = 2000$ (two thousand) per minute, and with 48 segments arranged in groups of three, its speed would be 1,000 per minute. The blank segments insulating the groups of the inner ring are connected to the extremities of a Rheostat Rh. Rh., which is enclosed inside the commutator and is designed to offer a path for the alternating current such as there may be, and prevent its absolute rupture at the period of change from one group of segments to the next; they also serve an important purpose in preventing a dangerous short circuit which would be occasioned by the inner brush bridging two groups of segments oppositely connected.

It follows as a matter of course that as the machine starts as a direct-current motor connected in an alternating circuit, rapid reversals of magnetism will at first be produced in all the iron cores, and these should be made of laminated iron to prevent undue loss by heating at the period of starting. The machine, in fact, starts as a direct-current motor, and automatically changes to a sort of synchronously alternating motor. When it gains its normal speed at this point it is self-regulating, and its capacity of doing work is a maximum.

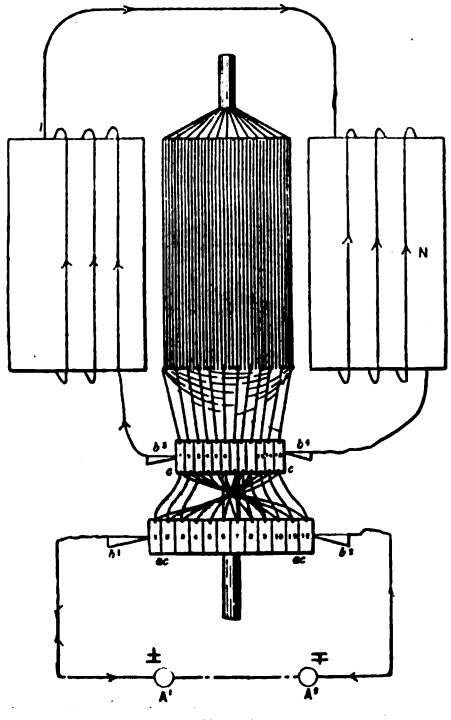

FIG. 6.

Fig. 6 shows a plan of the machine as constructed—it consists simply of an ordinary closed circuit armature in a single field; $c\,c$ is the ordinary collector, really a part of the armature circuit from which the brushes b^3 b^4 take a current of constant direction to the field shunt; $a\,e$ is the reversely connected commutator, and the brushes b^1 b^2 bearing upon this commutator are connected to the terminals of the alternating-current circuit.

I might add to the Paper the fact that the inner commutator, the one which is the ordinary commutator of the Gramme ring winding, does not perform the ordinary functions, as the brushes bearing on this collector require no adjustment, it being a rubbing contact from which the shunt-field circuit is taken as a derivation to the main circuit of the machine. With that exception, I think the machine is fully explained in the Paper.

DISCUSSION.

In replying to the discussion which followed the reading of the Paper,

Lieut. PATTEN said: The sparking being due to the electromotive force at the point of breaking, it will necessarily occur during the starting of such a machine, and more than ordinarily when it is out of synchronism with the alternating current. At the outset it can be easily seen that the alternating current is liable to be broken at a point where this electromotive force is high, and therefore the sparking would be very violent. I have endeavoured to obviate the trouble due to that cause in the machine—the device is shown in Fig. 5. If you will notice the circuits carefully, it will be seen that the circuit of the alternating current is never broken. If the brush comes on to one of the dead segments or shaded segments connected with the rheostat before the alternating wave has come to zero, it finds a path which is at first in parallel with the machine circuits, and then becomes a separate path for the alternating current during its change, whether this change begins at a high or low electromotive force. Of course, as the machine starts, this may happen at any period of the wave, and the brushes passing over these segments connect with the resistance at the end of the group, and before it has left the group the current is already short-circuited through this rheostat, so that the alternating-current always has a path and the sparking will not be excessive, judging from what little experience I have had. It will not start on full load. What he had spoken of as insulating segments are segments not connected with the circuit of the machine, but simply to the rheostat which is shown in the drawing, and this rheostat is intended to take the current at the time the brush leaves the group which is connected with the machine circuits and so prevents sparking. The current is broken when the machine is in synchronism at a point near its zero point. Of course, at 16,000 alternations per minute the interruptions are so short that the field could not readily lose its magnetism, but whenever there is a break in the current, there must be some slight loss due to that.

Mr. MAILLOUX: I should think that a machine of this kind, although it is of great theoretical interest and is an evidence of striking ingenuity, would be open to a defect arising from the fact that the current is a wavy one, no matter how rapid the periodicity is. Then there is always a very short time when there is no current. We may consider that the magnetising current through the shunt is a succession of waves. Consequently there would be an oscillatory tendency in the magnetism, a tendency to rise and fall with it. If the magnetic core is laminated and of soft iron, I think that it will be able to rise and fall quite readily; in other words, quite rapidly enough to follow the fluctuations of the current. We know that it does so in transformers. Of course, there is a slight reaction in the substance of the iron itself—its "viscosity"—due to hysteresis; at the same time, it is not sufficiently great to interfere with the rise and fall of the magnetism, and the more perfectly the core is laminated the more rapidly the rise and fall would take place, also the thinner the laminæ, so that if the magnetic field is made of a very finely-divided magnetic medium, and if the rise and fall can take place readily enough, it seems to me that there would be a certain amount of loss in consequence, which would be quite material under certain conditions, and also a certain amount of loss due to the reactions following from mutual induction in the

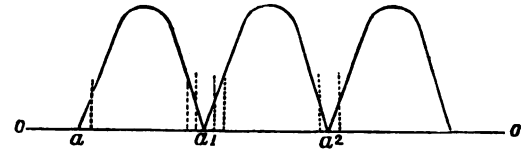

FIG. 7.

armature itself, because we can see that even when running at synchronism the current in the armature would be a succession of rises and falls, and although the magnetism of the armature is not reversed, yet the current is reversed through the coils, and that is not perhaps so disadvantageous as the fact that it is constantly rising and falling at a very rapid rate. I should think that the loss due to mutual induction, particularly in the presence of a magnetic body of permeability and susceptibility, such as the armature core has, would lead to a very important source of loss, and I should not expect that a motor built on that principle would show the efficiency which we might expect from other forms—for instance, as those forms suggested by Leblanc in France, and by Mr. Mordey in England.

Lieut. PATTEN: I have only to say in reply to that, that there is one evident misconception about the direction of current in the armature circuit. It is always the same. As to what has been said with reference to the induction due to the rise and fall of current, such loss is contemplated, and it is difficult to make out of an alternating current anything that does not vary. The essential fact, however, is that the current at work is due not only to the maximum and zero values of the electromotive force exerted, but to the current which is the result of the mean electric force, and that is the electromotive force out of which we desire to get the work. The current is of constant direction in the armature circuit, but it rises and falls as has been said, and the loss due to that has been contemplated. I do not recall any machine described by Leblanc, except those that he has referred to as Mr. Tesla's and Prof. Thomson's earlier form of motor. Beyond them I do not recall any machine in which these difficulties are not equally present. The current in the field will necessarily be a re-directed current. It would be represented graphically in the form I have drawn on the board (Fig. 7). The commuted current at work, or the electromotive force, to speak more strictly, would be cut off at the point a^1 we will say; if the machine is in synchronism at points a^1 and a^2 the interval would be a period of no current. The loss spoken of by Mr. Mailloux will exist during such a slight period of no current whatever, as occurs at the point between here and here. I think that a solid field would not probably give up its magnetism during that short period of time. A closely laminated field might do so.

Mr. LUDWIG GUTMANN: I think the motor just described is very ingenious, but we have, of course, to consider it in connection with the circuit. It is a step forward, because it can be so arranged as to permit the introduction of motors of different speeds on the same circuit. Nevertheless, the motor is of the constant-speed type, while in practice a variable speed is often desirable. The serious objection is that it has the high potential current in the motor armature itself, and in case of any trouble

Digitized by Google

arising, the consumer who has to handle it is immediately exposed to the danger of high-tension current in the main wires. Otherwise, I believe it would answer many purposes, because the motor will do its work well. It appears that the motor would not start with any load on it, and would need a loose pulley so as to get up to synchronism before the load could be thrown on. I do not think that this motor can be worked at low tension on account of self-induction. If such a motor should be placed on an ordinary alternating-current circuit of 1,000 to 1,500 volts, and there is any sliding connection and commutators to get loose or brushes to wear out, we should always have to send practical and experienced men to the spot, and they would be exposed to the 1,000-volt current, which would be objectionable.

Lieut. PATTEN: With reference to the high potential, of course, in the general description the source of alternating current is represented as any, of either high or low potential. The current is presumably one of suitable character to meet the conditions in which it is to be used. With reference to the further difficulty mentioned, accidents will happen with any kind of machine, either direct or alternating, while the other forms of motor have some advantage in having ring contacts and sliding brushes that require no attention. The disadvantages that are introduced by bringing in the use of brushes are incident as well to the ordinary forms of motors with which we are familiar. We are not so familiar with the kind that have no commutators that we have got used to their ease and simplicity of working. The second set of brushes are not, as I have said before, brushes in the ordinary sense, and do not require adjustment and care. If a high-potential machine is used, of course the ordinary precautions will have to be taken. It is not quite within the province of the alternating-current motor to make the alternating current safe for everybody who uses it.

Mr. GUTMANN: To produce five to ten horse-power we need a certain number of ampere turns in the field, which entails a considerably higher pressure than might be supposed. We must have an armature to perform the work and to obtain the torque. Consequently I think it is impossible to realise a large amount of power without using medium or high-tension currents for alternating-current motors. I should prefer a motor like Prof. Thomson's, in which the high-tension current is fixed—no rubbing contact; and I think Mr. Tesla has shown us one way in which to construct a motor without commutator or brushes. As it stands, we have increased self-induction, and we need a greater power and greater tension for this class of motor than we would if we had only to energise one of the two parts.

THE RENARD ELECTRIC TABLE LAMP.

The Renard primary battery, which was originally devised with a view of obtaining a light battery for driving the electric motors in connection with the Renard-Krebs dirigible balloon, is now being used for domestic lighting purposes, and it was recently employed to supply current to the arc and incandescent lamps lighting the rooms at the Société d'Encouragement on the occasion of the joint meeting of the Institution of Electrical Engineers and of the Société Internationale des Électriciens. The negative element of the Renard battery is platinised silver foil shaped into a tube, in the centre of which the zinc rod is placed. The liquid is a solution of chromic acid, hydrochloric acid, and sulphuric acid, and is contained, as a rule, in glass tube-like cells. The spent liquid, it may be mentioned, is a powerful disinfectant.

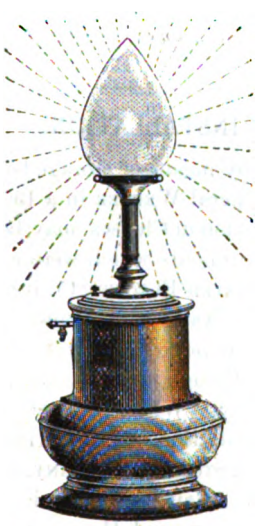

FIG. 1.

A 25-candle lamp, weighing 35lb. and containing a sufficient charge for from five to eight hours, is shown in Fig. 1. The battery consists of seven Renard elements connected in series, and it is capable of giving a current of 4 amperes at 11 volts for the above-mentioned period. In order to charge the battery the candelabrum is removed, and the seven zincs are placed in their respective apertures on the vulcanite lid and screwed up; the solution is then poured into the reservoir by the remaining aperture, and the candelabrum is replaced. The liquid is driven from the reservoir into the cells by means of the india-rubber ball p (Fig. 2), the stopper b being previously screwed down, and the tap r opened. When the light is no longer required the air in the reservoir is allowed to escape, and the liquid falls clear of the zincs. To empty the spent solution the candelabrum is taken off, the zincs removed, and the liquid is pumped into a glass jar by means of the aspirator p (Fig. 2).

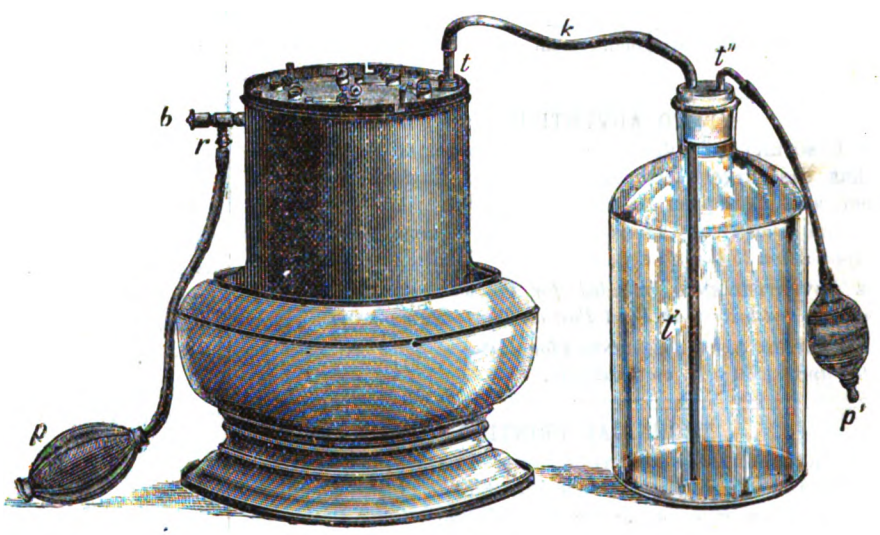

FIG. 2.

The composition of the liquid for one charge is as follows:—Water 5¼ pints, muriatic acid ·7 pints (400 cub. cms.), sulphuric acid ·67 pints (380 cub. cms.), chromic acid 2lb. 7oz. The price of these ingredients is about two shillings, so that the cost of the candle-hour may be taken at about one farthing.

This lamp, which is sold in this country by Aron Brothers, of Bridewell-place, seems to possess several advantages over many of the domestic electric lamps hitherto in use. The cleansing operations are reduced to a minimum, owing to the absence of crystal deposits, and the difficulties of mounting and unmounting, which act as such formidable deterrents to the employment of primary batteries, have been largely overcome. The acids employed are, moreover, such as are easily obtainable in the ordinary way.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, October 11th.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Inaugural Meeting of the Ninth Session of the Society at the Westminster Palace Hotel. Presidential Address on "Mechanical Engineering in Electrical Industries." By Prof. JOHN PERRY, D.Sc., F.R.S.

SATURDAY, October 12th.

CITY AND GUILDS OF LONDON INSTITUTE OLD STUDENTS' ASSOCIATION.

7 p.m. Fifth Annual Dinner at the Manchester Hotel, Aldersgate-street.

TUESDAY, October 15th.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture, "King Frost." By ARTHUR CLAYDEN.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny. Editorial, Publishing and Printing Offices.

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

THE CHELSEA INSTALLATION.

The system of distribution by means of storage-battery sub-stations, described by Major-General WEBBER in a British Association Paper, and now in operation in Chelsea, may be regarded as the final outcome of the experiments which were commenced on a large scale by the CONSOLIDATED ELECTRIC COMPANY at Colchester in the spring of 1884. As is well known, this early attempt, from which so much was hoped at the time, resulted in failure; but the experiment, though a costly one, proved not to have been wholly thrown away. When in 1886 it became necessary to abandon the installation, Mr. F. KING and the officers of the ELECTRICAL POWER STORAGE COMPANY, with whom he has since been associated, retained a firm belief in the inherent soundness of the scheme, and they devoted much of their attention to its improvement in points of detail. It was early perceived that the "sweet simplicity" of the single "rock-over" switch which had been deemed sufficient at Colchester could never fulfil all the conditions which are imposed by the practical working of such a system of distribution, and the number of supplementary devices found necessary was gradually augmented until the highly complex organism described by General WEBBER had been evolved. It is impossible to deny that these complicated automatic appliances—much as we admire the ingenuity displayed in their design—do form a weak point in the system. Whether the weakness is such as to prove any serious obstacle to its progress, time alone can show. We sincerely trust that it will be found that these appliances are as successful in operation as they are admittedly skilful in conception.

It will now be interesting to note the chief points of difference between the Colchester installation of 1884 and the Chelsea installation of 1889. First, there is the improvement in the batteries to be noted; the batteries used at Colchester were

Digitized by Google

made by the CONSOLIDATED ELECTRIC COMPANY, and were of the Planté type. The plates were made up of thin strips of lead, pressed or coiled together, and having a thicker tape coiled round them, the whole being burnt together at the corners to obtain the necessary rigidity. With this type of cell it was impossible to obtain that uniformity of structure throughout the battery which is so essential to its preservation. To make matters worse, the insulation of the Colchester cells was badly arranged. The cells were supported on cast-iron racks, resting on porcelain insulators, which latter rested on the bare floor. The modern method of mounting cells is by means of oil insulators, resting on wooden racks, which at Chelsea are supported on cast-iron standards. We need not refer in detail to the difference between the Consolidated cell of 1884 and the E.P.S. 1888 type, the latter being already so well known. Perhaps the chief practical advantages lie in the large clearance which is now left between the lower edge of the plate and the bottom of the cell, and above all in the uniformity now attained in the manufacture. In capacity for discharging a heavy current for a short period without suffering damage, some advance has also been made, and of course the care of cells is now better understood.

An important distinction betwixt the two methods lies in the fact that whereas in Colchester two complete batteries, each capable of supplying the entire output, were employed, at Chelsea there is only one battery, divided into two halves, each half being charged at different times during the hours of daylight, and used in parallel during the period of maximum demand.

Turning next to the method of operating the automatic switches, we find that the principle remains unaltered. In each case, towards the close of the charge, a "master cell," whose evolved hydrogen has been collected in a small gasometer, is entrusted with full responsibility. In the earlier case, however, the pressure of the gas merely operated a plunger, closed a local relay, and over went the rocking-switch with its thirty-six mercury contacts, reversing the connections of the two batteries, the newly-charged battery being put on the supply circuit, and the second taking the place of the first on the charging mains. Now, we are not aware that any complete account of this switch and its exact method of operation has ever been made public. There is a long verbal description by Mr. KING in *The Electrician* of June 14th, 1884, but it does not tell all we should like to know. It is, however, sufficiently evident that this apparently quite sudden breakage of a 2,000-volt circuit was a ticklish thing to deal with. We do know that these switches proved a serious source of trouble, and we expect that the dynamos—although it is true that they were separately excited—also suffered. Now for the Chelsea device. The whole operation, although perfectly automatic, is effected with deliberation, requiring one minute to complete itself. First a separate resistance, taking a current equal to that of the half-battery, is switched in parallel with it; at the same time half-battery No. 1, now fully charged, is switched on to the supply circuit in parallel with half-battery No. 2. Next the latter is put in parallel with the resistance on the charging mains, and finally the resistance is withdrawn. In these operations several solenoids or electro-magnets fulfilling different purposes come into play, and a relay transmits a current by a special wire to the generating station, and at the critical point cuts off steam from the engine. How this affects the other storage stations, which we take it may or may not some day chance to be in another stage of the same series of operations, we are not told, and it seems rather a formidable problem to work out on paper. We should also like to have more information than we at present possess as to the arrangements adopted in the dynamo room.

As to the regulation of the E.M.F. on the house mains at Colchester, so far as our information goes, no special precautions were taken, but at Chelsea we have a set of four counter-E.M.F. cells with their accompanying tell-tale wires, and automatic switching appliances by which this important matter is looked after. The details of this part of the apparatus are again very complex. We find a fine wire coil in parallel with the feeders, actuating a relay which causes "two double-acting solenoids" to operate switches which traverse sliding contacts connected with resistance coils. Then there is an ingenious "E.M.F. governor," with a temperature compensator containing mercury and alcohol, and so on.

At Colchester we have already noted that the battery was switched on or off the supply circuit as a whole, whilst at Chelsea one half-battery is on in the daytime, whilst the two halves are in parallel during the hours of maximum demand. General WEBBER does not seem to have explained the *modus operandi* whereby the second half-battery is brought into parallel with the first, when the increased output renders the step necessary; but doubtless there is an appropriate set of automatic jacks-in-the-box dedicated to this task. Then, again, there are the continuous-current transformers which are to be brought into play (automatically, we presume) when the growth of the system demands a still greater output. Perhaps all this is included in the "many minor very important and interesting features" which the gallant General, for want of space, was unable to describe.

It is abundantly evident that this system has had bestowed upon it an amount of, we had almost said, loving care and ingenuity which at least deserves, as we trust it will command, success. But if this should unhappily not be the case, it would seem probable that Chelsea will perish under the weight of excessive elaboration, as Colchester fell a victim to its undue simplicity.

DISTRIBUTION OF ELECTRICITY IN CHELSEA, &c., WITH ACCUMULATORS AS THE MAIN SOURCE OF SUPPLY.*

BY MAJOR-GENERAL WEBBER, C.B.

Accumulation of electricity is the first necessity to those who study the conditions of its supply to consumers living in a thickly-peopled district, and has been so since the notion of distribution to an inhabited area from a centre of generation has taken a practical form. In face of the many cases in which distribution has been undertaken without accumulation, this may be regarded as a bold statement. But I can only say that I have not met one who, having adopted it, does not candidly admit that the advantages of the presence of means of accumulation are undeniable. The financial question has governed the advance of the industry, and the scattered nature of the first demands for a supply of electricity has without doubt led to the adoption of high-pressure distribution when every other consideration would have appeared to suggest that all first attempts should have been made at low pressure. The insulation afforded by the use of aerial conductors has led to partial success. If the distribution had had to be carried out by underground mains from the first, the deterrent effects of the experience that would then have had to be gained might have led to different procedure, and even the financial aspect of the question might have gone through different phases. Some will assert that the industry in this country could not have made a start at all, in the face of cheap lighting gas, if it had not been pioneered by means of economical conductors, however temporary, and without attempting to accumulate. But, after all, it was only a question of cost, and it is certain that had the capital been forthcoming in 1886, it would have been as easy to have obtained success with the system I am about to describe as now. All the essential means now at our disposal, except matters of minor detail, were then equally at hand. This is proved by the fact that the proposals prepared and made in 1886, immediately after the Chelsea

* Paper read before the British Association in Section G, Newcastle, September, 1889.

Digitized by Google

Provisional Order was approved by Parliament, are similar to those which have been carried out in 1889. It was as clear then that accumulation and distribution underground was the true solution of the problem for a comparatively densely-populated district.

The district of Chelsea was selected, not as the wealthiest or most densely populated, but because it was destined then, and since then, and for some time to come, to be one in which the dwellings are in a process of reconstruction. It was in 1886 as evident as it is now that the impediments in the way of getting old houses wired is a serious hindrance to the rapid spread of the demand for current, and that this impediment is minimised under that condition. In the interval many of us have been fascinated by the high-pressure systems. I think myself fortunate that, I may say, accident prevented me attaching myself to any scheme dependent on that condition, together with alternating currents, for domestic supply. The temptation was rather strong for one reason at least—that is, that some capital was forthcoming to promote the latter, while very little could be got together to carry out the former plan. Although it is not sound, the engineer sometimes *does* surrender his better judgment when money leads.

The Chelsea system may be described in the following terms:—Accumulation of the main supply from a generating station in storage stations, situated at suitable distances from one another, combined with the following—

(*a*) Charging the accumulators at high pressure, and discharging for distribution at low pressure, and effecting the changes necessary to the same by special automatic arrangements placed in each storage station.

(*b*) Supplementing the main supply by means of continuous-current transformers.

(*c*) Distributing by means of mains laid down in a network.

(*d*) Maintaining a constant pressure by means of the introduction into the discharge circuit of counter E.M.F. cells, and by means of feeding points judiciously placed intermediate between the storage stations.

(*e*) The use of underground conductors throughout, laid so that the cables can be drawn in and out, and renewed or repaired whenever necessary, without disturbing the ground.

It has been remarked that one of the causes of interference with the spread of the use of electric light is the outlay entailed by the necessity to introduce conductors and fittings for distribution and consumption within the house. Members of a society called the Dynamicables will remember a Paper on this subject, read a few years ago by Mr. Crompton, when he expressed a hope that the cost of such work might be brought down to 15s., without including the lamps and their fittings, for each point where the light is required.

The fact that this figure has rarely been realised, and more often doubled, is not, however, the chief impediment. It has been suggested that the undertakers might carry out the work on a deferred payment system, but this would meet only a limited number of cases. The main cause of impediment at present is the condition of the situation as regards landlord and tenant, by which there is no inducement to the former to do more for his tenant than his lease obliges him to do, and by which there is no compensation to an outgoing tenant for outlay on *bonâ fide* improvements. The fitting up of houses for gas consumption has now, by competition, been brought down to about 7s. for each point where a burner has to be fixed, above a certain minimum number of points. Except under Government Departments, I have rarely encountered any form of specification for such work. I have never yet heard of gas engineers being called in to advise on or pass work for the distribution and consumption of gas inside buildings, beyond questions of meterage and regulation of pressure. The consequence is that the proportion of gas which from one cause or another escapes unburnt, and enters into combination with the air we breathe, is very considerable in proportion with the gas we actually use to give us light, varying from one or two to seven or eight per cent., some due to defects in pipes, more to defective burners. For economy, the same work in connection with electric lighting is rapidly tending to fall into a similar condition, and were it not for the practical necessity to take precautions to protect buildings from fire risk, and the public from injury to person, which has given rise to Fire Insurance and Board of Trade rules, the consumers of electric current ere long would find themselves in a worse condition than if they stuck to gas as an illuminant, for reasons in connection with leakage which are evident to all my hearers without any description.

In Chelsea we have from the first endeavoured to counteract this evil by, first, holding aloof from all appearance of having any pecuniary interest in the work of fitting up houses in the area of supply; second, supplying to the inhabitants, either free of cost or for a small fee, a copy of our standard specification for such work. This form is compiled so that it can be used under varying conditions when filled in by a competent engineer. A sample of it is attached to this communication. The necessity for care and precaution in this respect, and the consequence of a little more trouble and expenditure to the public than has hitherto been given to the subject of lighting, is, however, well repaid by the advantages to health and comfort by adopting electricity as an illuminant. This is the sole lever with which electric light undertakers have to work in face of—

1. Competition with cheaper illuminants, which in the case of mineral oils are one-third to one-fourth the price of electricity, light for light, both as regards first and annual cost.

2. Indifference to the question of health so long as the danger is not very apparent, only being very slowly counteracted by the spread of knowledge.

3. Rules and regulations which everyone acknowledges to be salutary, but which must hamper the industry at first, particularly so as the rival illuminants are not subject to anything of a similar kind.

The apostles of electricity as an illuminant have, however, no fear that sooner or later it must triumph, and that the poor as well as the rich will eventually enjoy its advantages; and that those who have given labour and attention of the most exceptional nature to produce perfection will eventually reap their reward.

Leaving this branch of the subject of consumption, it should be stated, *en route*, that the meters in use in Chelsea are those of Aron, Chamberlain and Hookham, and of the Brush Company. The first, which is used in this country under a royalty from Messrs. Ayrton and Perry, and which is at present in a large majority, has undergone considerable modification and improvement in construction lately, with the result of greatly simplifying its action. The meter as now employed has no starting gear as formerly, to which objection had been found to exist. The meter is compact, being about 2ft. 5in. long by 15in. wide and 8in. deep. It is constructed of two sets of clockwork, the deviations of which are to be indicated, mounted side by side in the same frame with a differential counter placed between the two sets of clockwork. The clockwork is driven by a spring. The differential counter consists of two crown wheels, having at the same time a cylindrical gear opposite each other. Between the crown wheels a planet wheel is arranged gearing with both the crown wheels, and is made so as to turn at the same time round its own centre, and so as to roll along the cylindrical gear of the crown wheels, and it is balanced by a counter-weight. The vibrations of a pendulum of one of the sets of clockwork is either accelerated or slackened by the influence of a coil through which the whole of the supply current passes; the pendulum has a permanent magnet or armature attached to its end, and is so arranged as to swing immediately over the centre of the coil. The clockwork being synchronised, there is no movement of the indices on the dials when no electric current is passing, although the clockwork is running continuously. The clockwork runs for six weeks, but we find it advisable to wind them once every month to ensure them from accidental running down before their time, and thus stopping their use for registering. They are easily fixed in position by a workman. It is only necessary that care should be taken to set the pendulums so that they hang immediately over the setting pin placed for the purpose. The man then winds the meter, starts the pendulums swinging, and the meter is then ready for work and for the purpose of recording when the electric supply is started. These meters have given most satisfactory results during the six months we have had them in use. The meter registers in ampere-hours, *i.e.*, each unit registered by the index dial has to be multiplied by a constant supplied with each instrument. For the convenience of customers, a multiplier is supplied by us with each meter card, and instructions printed stating that the amount registered by the indices at any time multiplied by the multiplier given on the card enables them to ascertain in Board of Trade units the consumption of current. The meter of Messrs. Chamberlain and Hookham has been so thoroughly described this year by Mr. Hookham before the Institution of Electrical Engineers that I need not give any of its details. Our experience of its working is at present very limited.

The Brush Company's meter (Fig. 1) may be described as follows: The meter consists of, *a*, an electrically-driven pendulum, suspended over an electro-magnet, a_1, but slightly at one side of it. Near the pendulum is placed, vertically, a solenoid, *b*, in circuit with one of the conductors to the lamps; the core is carried by a light rod attached to a spiral spring suspended from above. To the side of the rod towards the pendulum is fixed, in the plane of oscillation, a notched integrating plate, *c*. As the core is drawn down by the current passing through the solenoid, or lifted up again by the spring, the notched plate is also raised and lowered. An horizontal arm, *d*, resting on two rollers, travels backwards and forwards with the movement of the pendulum, but the distance travelled, or amplitude, is controlled by the notched plate, being greatest when the core is drawn down so that the horizontal arm travels as far as the uppermost notch, and smallest when the core is elevated so that the arm is stopped by the notch on the edge of the widest part of the plate. The arm carries a small catch, which, when it travels to the left, drawn thither by the spiral spring at that end, pushes round the last and lowest wheel of the counting gear, *f*. For instance, when the arm moves through the shortest distance the

Digitized by Google

wheel is pushed round only one notch. This smallest movement may be regulated to occur when one-third of an ampere is passing through the solenoid, and thus accurate metering is ensured by the construction of the parts being such that for each sway of the pendulum the last wheel of the gear is always advanced through an angle exactly proportional to the current flowing at the moment. The electro-magnet, a_1, used for driving the pendulum is on a shunt from the supply main, the circuit of which is closed and opened by a relay, e, which comes into action with the smallest current that the meter is required to measure. I have described the main features of this apparatus only, but there are other minor ones; for instance, a contact-making device worked by the pendulum for the purpose of properly timing the impulses given to the electro-magnet (a_1), with which I will not occupy the meeting.

A marked feature in the system of distribution by continuous-current at low pressure is the absence of the transformer from the premises of customers, and the small space required in the house for the meter and cut-outs. Although the space required for a transformer is not theoretically large, in practice it is found that its installation is a more serious cause of expenditure and interference with structure than the advocates of its use lead us to suppose. In very few houses is to be found a chamber suitable to receive a transformer of ordinary size. In 1887 I inspected one of the first installations

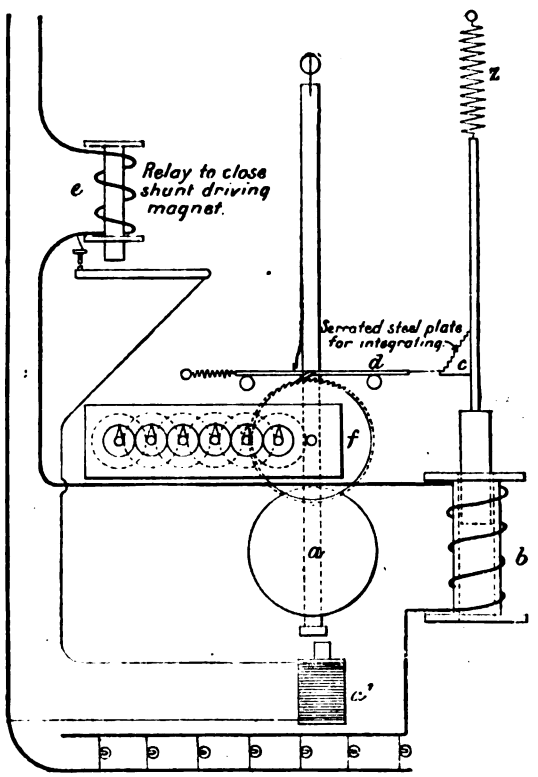

FIG. 1.—Diagram of Brush Company's Meter used at Chelsea.

under the system, namely, at Lucerne, by Ganz and Co. There I found the transformers in cupboards, and heating so as to colour the surrounding woodwork. The insurance companies in England would not have permitted them to remain a day in such a place. It is wrong to suggest that the installation of a transformer does not entail an expenditure much in excess of its actual cost. This condition affects materially the comparison between the first cost of rival systems.

We now come to the work outside the customers' premises, and I am able to show you a diagram illustrative of this part of the distribution. The area (Fig. 2) comprises portions of the parishes of Chelsea and Kensington. Its superficies contain about 867,000 square yards, or about 1/3·5 of a square mile. This area, divided into storage areas, in each of which a storage station is, or being, placed, allows to each such sub-area a space represented by a square of 415 yards a side. The generating station is marked X, and in the same building is placed a storage station. The other storage stations are marked O. Of these there are five in all. The points to which feeders are taken are each marked +, with letters to most of them. Each storage station itself is also a feeding or E.M.F. point. At present, the feeders vary in section between 61/12 and 37/13, according to the length and the current it is estimated they will be called on to conduct. The distributing mains, which are laid so as to supply the houses in every street prescribed by the Act as compulsory, sometimes in front and in some places at the back, connect all the E.M.F. or feeding points, and vary in sections between 37/13 and 19/16. The pilot wires from the storage stations to the generating stations, and from the E.M.F. points to the regulators in the storage stations, are of small section, and have their separate "ways" in the conduits or cases. All the "ways" can receive cables of larger dimensions, so that the section, when necessary, can be increased. And, besides, in each line of conduits spare "ways" are provided for future use. Up to the present time, about 10,575 yards of cable have been drawn in and put to use, besides some thousands of yards of pilot wires. By the end of this year these figures will be increased more than half as much again. The joints in the E.M.F. boxes, between the feeders and the distributing systems, are made by soldering the cables to a copper jointing piece, made as shown in the diagrams (Fig. 3) on the blackboard. All cables, after being drawn in and before being jointed, must show an infinity insulation resistance test before being passed. The test is made at a pressure of 100 volts. In many instances, after joining up sections of the network, and testing them together, including joints of house services, the disconnected ends sealed, the same result has been obtained.

The question of the cost of the mains and house connections is one which forms a most important factor in the undertaking. After careful consideration of the subject from all aspects, the use of bare copper conductors was discarded. With the permission of the War Office, experiments had been made by me at Pimlico with bare copper conductors so long ago as 1884. In making the tests I had the kind assistance of Prof. Ayrton, F.R.S. The conductors were made of uncovered copper wire cables, I think 19/12. They laid in notches made in insulite saddles seated in cast-iron troughing 6ft. long, jointed end to end, and having covers also carefully jointed; the cables were free of all approach to contact with the surrounding iron, and all the joints of the iron casing were watertight, or believed to be so. Tests were made with a 50-ampere current at an E.M.F. of 80 volts at intervals of some months after the wire was laid underground, and it was tested under the two conditions of having the intervals around the cables left vacant, and

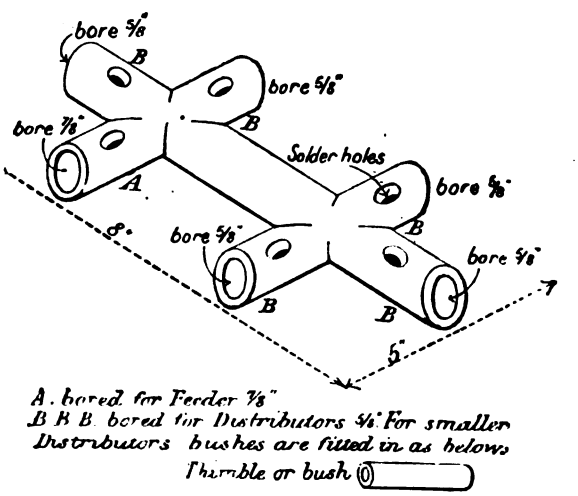

FIG. 3.—Copper Jointing-Piece for Mains.

filled in with paraffin wax. The results led to the complete abandonment of the plan, and of the patent which had been taken out for it. There is a strong resemblance between it and the mains which are being now laid down in the district in London known as the St. James's. For the sake of the industry, in which so many are interested, I trust that those responsible for that work will meet with greater success than I did. Experiments were made in 1886 and 1887 with the view to obtain some form of conduit which afforded a separate "way" for each insulated flexible cable; and so that the old and well-known *drawing in and out* system of the Electric and International Telegraph Company, founded on an experience of many years, might be followed. A metal tube for each cable was too costly. The bundle of cables in one iron pipe would prevent the possibility of drawing in and out. The material of bitumen concrete, which could be moulded to any form, presented itself, and the patent of Butler as to the mixture was followed. The Callender Bitumen Company undertook to carry out the work, and a sample line of casing and cable drawn in was laid, and was under trial during the period of one year at the Borough-road premises of the Anglo-American Brush Electric Light Corporation. Out of this has grown what has become known as the Callender-Webber system, descriptions of which have been given elsewhere. All that was anticipated of its advantages have been more than realised in Chelsea.

Although the part of Chelsea in which operations were carried on should present the fewest difficulties to be encountered in any part

Digitized by Google

of London, it was found that there was little or no local knowledge as to the size or position of the cellars of houses, and that no one could tell where the arches stood, or where the water and gas mains and services actually lay. As the access to house-service boxes must be easier if the main is in the footway than if it is in the roadway, every effort was made to keep within the edge of the kerb. But to do this in many places was found at first to be impossible, and the cases had, in several places, to be laid under the roadway. In such a position it was necessary to keep them outside the gas and water mains, and as the local authority prescribes a minimum distance of 3½ft. between these mains and the kerb, and 1½ft. between mains themselves, it followed that those for the electric light had to be 8ft. or 9ft. from the kerb. The future inconveniences arising from this are so many that it has now been decided never to lay the "cases" anywhere under the roadways, except at crossings, unless absolutely physically impossible to do so. The material of which the "cases" are made lends itself to this, as it can be made in flat sections, with a single tier of holes, O O O, and in such a form occupies very little space in depth. The facility of bending it is also a great aid in passing obstacles. There *have* been instances in which we have been able to get in "*casing*" in advance of the services of the gas and water companies, and in those we calculate that the cost is reduced at least 10 per cent. The great ease with which the material of which the casing is made can be cut simplifies the operation of inserting a house-service box on the mains that have been previously laid. Only that portion of the case need be removed which contains the ways in which lie the distributing mains. The box is best formed of brick in cement, and the top of cast iron, with a waterproof cover flush with the footway. The same manner of construction has been found best for draw-boxes, the iron tops of which are either L or T shape, also the E.M.F. boxes, where the feeders terminate. In the latter case the ordinary street manhole cast-iron top has been found to answer very well the purposes of a cover. Practice shows that if the sides and bottoms of the box were also made of iron, a great variety of patterns would be required, as the conditions vary at every point, so that brick in cement for all these boxes is the best material. A specification of the manner of conducting the work is in use, and a copy of it is attached to this communication. If care and attention is given to the simple rules for laying the casing, no difficulty is encountered with the cables. A true and smooth way is provided for each, so much so that in rare cases of need from one cause or another no difficulty has been found in pushing through from box to box one of those screw-jointed rods used by sewer men or chimney sweeps.

It will be gathered from the features of the system I have referred to that considerable economy in excavation can be secured by its adoption, in actual cost of the "ways" for the cables, totally avoiding the need for special castings for bends, and also in all the operations of branching-off and jointing. In comparison with the bare copper systems, the saving in towns in the cost of removing the soil to make space for the conduits is very considerable. Of the durability of the material, resistance to strains, and conditions of temperature, so far the proofs have been very satisfactory. But, as I have already stated, its foremost advantage is that it enables us to comply with the fundamental conditions of successful maintenance by permitting of the easy and rapid removal of faulty sections of cable, and the renewal of the same. Under such circumstances, with low-pressure distribution, a high standard of insulation resistance may be dispensed with, and a further saving in outlay effected. For let it be remembered that failures of the insulation of underground distributors of electricity will not occur by the gradual deterioration of the dielectric throughout its length, but by the existence of exceptional causes for its decay at isolated and unexpected points. Although the substance of which the Callender-Webber casing is made is dielectric, yet no reliance is placed on it even as an assistant to the insulation. The slight porosity of the material, and the

impossibility of making an absolutely watertight joint at every point where the lengths are united, at present precludes the idea of complete exclusion of moisture. It will be seen that this system lends itself to the manner of distribution already described by bringing within the range of practical experience the provision of the necessary number of "ways" for charging, feeding, and distributing mains, all of which along the same route may be lying contiguous to one another. The reference to it forms part of the description leading up to an examination of the basis of the system of distribution, in which accumulation constitutes the chief source of supply, and not a mere auxiliary. In such a system the generating station is even subordinate to the storage stations.

Given an area, and having determined what may be called (1) the active demand, and (2) the possible ultimate demand, and having decided to provide for the first, with the power to meet the second at some future date, the first thing is to lay it out in storage dis-

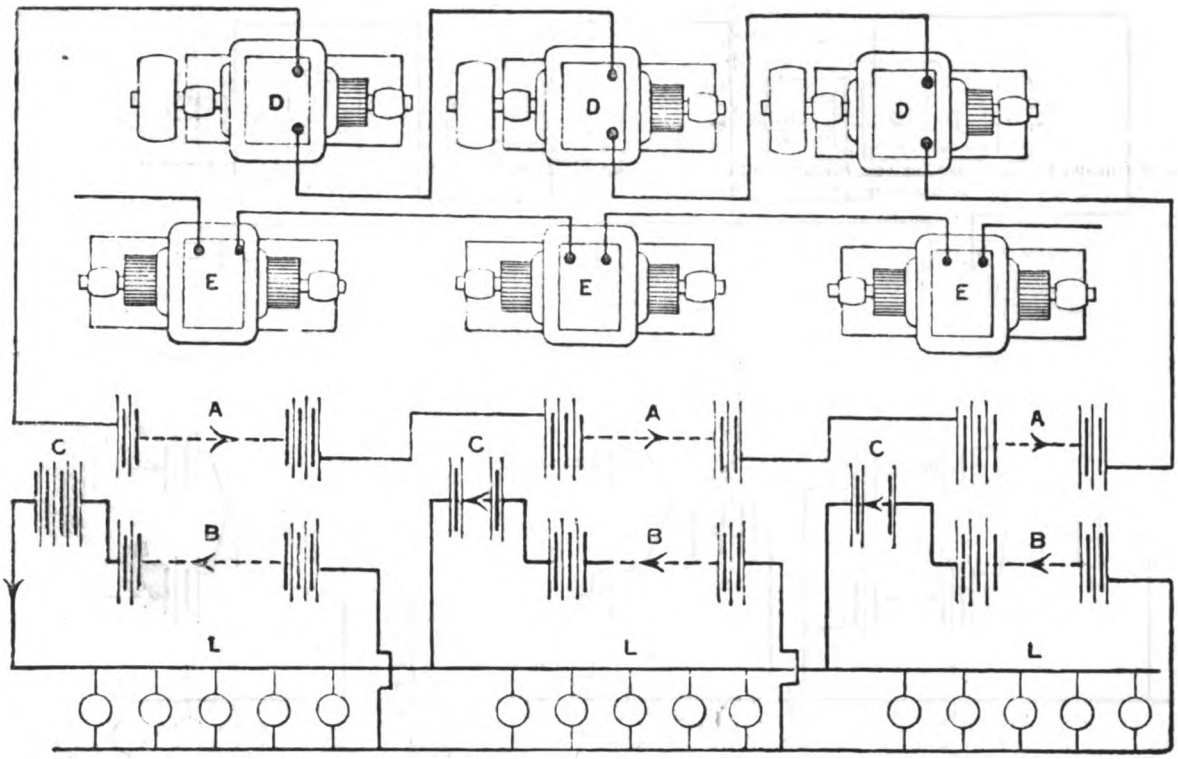

FIG. 4.—Arrangement 1. Dynamos charging First Half of Batteries.

tricts, always subject to the power of securing sites, and next, to fix the positions of the points to which feeders should be carried.

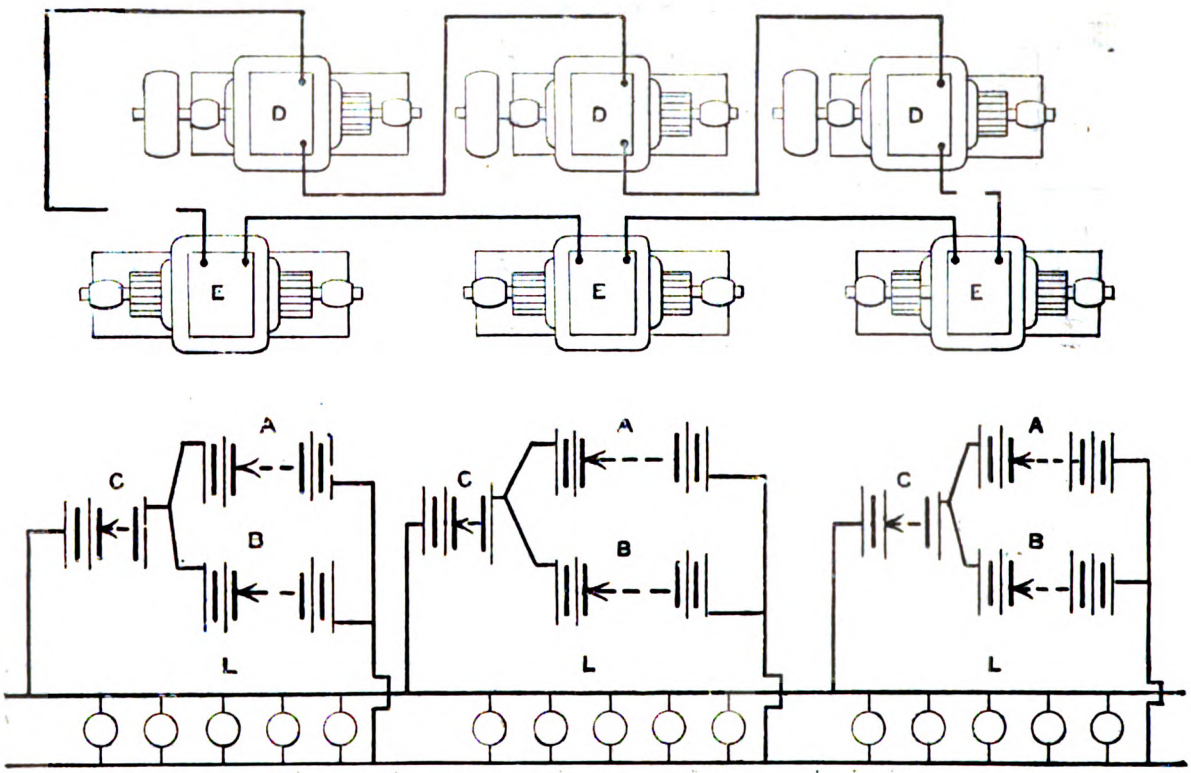

FIG. 6.—Arrangement 3. The Two Batteries Discharging in Parallel.

This would be a difficult thing were it not for the elasticity afforded by the network system, and by the power of varying the section of copper in the mains, which is simplified by the use of "ways."

one-third, or 70 of these. The distribution being at a pressure of 100 volts in the distributing mains, or 106 to 108 volts in the feeders at the station, a discharge of 600 amperes, to give 530 effective at the lamps, allows an ample margin, and this is afforded by the two half batteries in each storage station discharging at the same time.

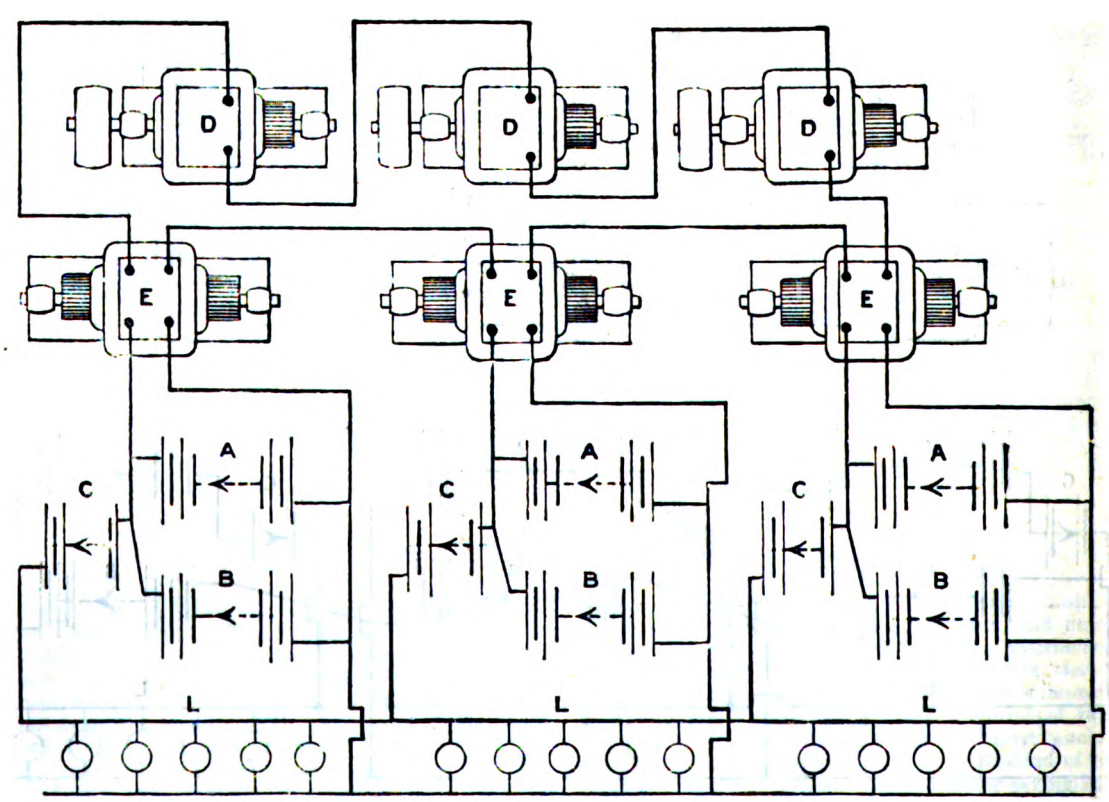

FIG. 7.—Arrangement 4. Continuous Current Transformers in Parallel with both Halves of Battery.

Our estimate in Chelsea to meet the "active demand" has been to establish one storage station to each 210 shops or residences, and to provide capacity for 27 30-watt lamps being in use at one time in

Each half battery consists of four sets of 54 L 31 1888 type E.P.S. cells, or a total of 432 cells. On exceptional occasions, one of these stations may be required to discharge at the rate of 800 amperes,

Digitized by Google

and will do so without injury to the cells. Although 1890 lamps are estimated for, the capacity of the station is for a normal 2,000 lamps, and, as has been stated, for an exceptional maximum of 2,500. The possible ultimate demand is a thing that I believe no one at present can estimate. Of course, any of us may make the statement that every dwelling *must* take the electric light, and that it *must* come, and it is easy to sneer at any scheme which does not now provide for such an end; but from the actual experience I have had, it is clear to me that the question is still rather obscure, and that end still far off. Meantime the Chelsea system provides for an increased capacity of 50 per cent. on the normal of 2,000 lamps—*i.e.*, up to 3,000 lamps—by the use at each storage station of a continuous-current transformer which will be put to work and yield its whole output during part of the time of maximum discharge, namely, between six and nine p.m. To those who put capital into the undertaking of electric lighting, it will be of interest to know that the calculations made on the basis of one-third of the houses requiring the light in five such areas as have been mentioned, and in the proportion named, show an excellent return on the investment. I only allude casually to this point, as the financial calculations of the subject do not enter into the scope of a communication to the Association.

I now arrive at the part of my subject when it is necessary to refer to the installation of the *storage stations*, and to state that, beyond a reference to the capacity of the generating and charging unit, I do not propose to give any description of the generating station, which, by the way, I do not refer to under the usual term of *central station*, as it need not be placed in any way centrally with reference to the group of storage stations for which it is required to generate charging currents. These charging currents are given by separate engine and dynamo plants, one for each station; in the case of Chelsea, 75 horse-power Willans and Robinson's well-known engines, and 37½ unit Victoria Brush dynamos, which are capable of giving a current of 75 amperes at 500 volts. The diagrams represent:—First (Fig. 4), three of these plants in series charging one of the half batteries in each of three storage stations, the lighting being maintained by the other, or second half battery; and the pressure in the distributing mains being regulated by cells which give a counter E.M.F. In the second (Fig. 5), the three plants are shown charging the second half batteries—those which having been previously charging, are now discharging to the distribution system. Regulation is still maintained as in the first position. In the third position (Fig. 6), there is a cessation of charging, and the two half batteries are shown to be discharging together in parallel. Regulation is maintained as before. In the fourth position (Fig. 7), continuous-current transformers are supplying current to the system in parallel with both halves of the batteries. The apparatus for effecting the various transpositions of the secondary batteries in the storage stations, and for maintaining the pressure constant in the mains, is automatic. The movable portions are worked by the energy which would otherwise be wasted in the counter E.M.F. cells, which are used for regulating the pressure in the distribution system. All the actuating portions of the apparatus require current at an E.M.F. of only four or five volts.

(*To be continued.*)

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 28, 1889.

Since the recent introduction of the alternating-current system on a practical basis in this country, there has been a great deal of interest taken in the subject of long-distance incandescent lighting, and, as usual in this country when interest is taken in anything, the attempt has been made in a great many cases to reach conclusions. Instead of theorising on the subject, some of the companies have pushed their ideas into practice, and the result is that we have already a large number of local companies doing an incandescent service whose last lamp is several miles from the station. In fact one hears almost daily of incandescent lamps' circuits 10, 15, and 20 miles long, and if this sort of thing is kept up the arc circuits will be nowhere as compared with the incandescent for length. A good deal of this seems to be the mere straining after sensational effect and the rendering of service in which there can be very little profit, but it goes on all the same, and it is interesting as being one of the marked tendencies of the day. A very striking instance of this character has just been afforded by the Heisler plant put in at Ottawa, Illinois. Early in the present year the Illinois Valley Light and Power Company decided to put in a plant to be run by water-power, and adopted the Heisler system. The work of installing the plant had actually been begun when the company found that the necessary water-power was controlled by parties who were not favourably inclined toward the enterprise. This was rather disheartening, but instead of dropping the work, or of going to the expense of putting in a steam plant, the company immediately made up its mind to get water-power elsewhere. It thereupon sent eight miles away from Ottawa to the town of Marseilles, where it secured all the water-power that it wanted, and from that point it ran its incandescent circuits into Ottawa along the bank of the river. Some idea of the work that has been done may be formed from the fact that over 45 miles of circuits have been strung. One of these is, as stated, to Ottawa, a distance of seven or eight miles, another of 10 miles to Utica, and a third of five miles to Seneca. In each of these places incandescent lighting is being done in the houses and in the streets. For the trunk lines a No. 8 American gauge copper wire, waterproofed, is used, and the circuits also include 12 miles of No. 11. This is, I think, a rather striking example of the new class of work that is being attempted, and which, I think, we are likely to see more of in many parts of the West, if not also in numerous Eastern towns. Another illustration of this kind of long-distance work is shown by the Westinghouse plant recently installed at Englewood, Ill., one of the recently annexed suburbs of Chicago. In this place the lights operate on the familiar Westinghouse alternating system, and are from two and a-half to nearly five miles apart. One remarkable feature of this installation is that the station is an adjunct to a big planing mill. No separate steam plant is employed, the steam being obtained from the large boilers used by the mill itself, an extra boiler being held in reserve. The engine running the mill is a 400 horse-power Wheelock, and the dynamos are belted to the shaft running therefrom. The fuel costs practically nothing, being sawdust and shavings, which are shovelled in one motion from the vault into the furnace, the brick vault being placed a few feet in front of the furnace, and the sawdust and shavings being deposited therein by a system of fans and blowers, that convey it along in galvanised iron pipes from the various machines. Thus all expense for carting or handling the refuse of the mill is done away with, and the shaving has hardly been ripped from the plank before the energy that it stored up is making itself manifest in some incandescent lamp five miles away.

There has recently been quite a little discussion in the papers here as to what constitutes a secondary battery, two of the prominent parties to the discussion being Mr. E. R. Knowles, of the Mutual Company, in Brooklyn, whose storage-battery system I have given some details of lately (*Electrician*, August 2, p. 329), and Mr. G. B. Prescott, jun., the electrician of the Electrical Accumulator Company manufacturing the Faure battery. This discussion is not so theoretical as it might seem, because it involves the scope of the recent decision of Judge Coxe, whose dictum, which was quoted approvingly by Mr. Preece, was that "a secondary battery is one which gives no current of itself, but is active only when so rendered by current from an independent source." Mr. Knowles has contended that there are a large number of primary batteries which can be practically constituted storage batteries by the action upon them of an independent source in the same way as a secondary. Mr. Prescott rejoins that one of the distinguishing characteristics between true secondary batteries and primary batteries capable of partial re generation is, that whereas the electrodes of a secondary after a complete discharge remain precisely the same in weight as they were when new, the electrodes of a primary lose and gain weight, the positive being entirely consumed while the negative generally increases in weight. Another point at issue, and quite a material one, is with regard to the manufacture of plates from active material in the form of dry powder. Mr. Prescott states that he has made numerous endeavours to construct a dry powder battery, but has met with only a degree of success, not approaching the perfection attained by the Faure process. Mr. Knowles claims that he has made plates filled with dry powder

Digitized by Google

compressed by a hundred tons pressure, which are very superior, and which, while being very dense and hard, are still so porous that if held in a horizontal position and moistened on the upper side the moisture will readily penetrate the whole mass and fall from the other side in drops. In other words, the pressure, while increasing their coherency, has in no wise injured their porosity, and Mr. Knowles believes that the limit of density has not yet been reached in practical work. The bearing of all this is apparently upon the contention of the Julien Company that they make their plates out of dry powder, and are pretty well satisfied with the results they obtain.

A new electric motor has lately been brought forward by Mr. W. Baxter, who was for some time connected with the Baxter Motor Company, of Baltimore. This motor is of the multipolar type, having its poles all on one face, so to speak, circularly arranged; and another feature is that it has three brushes on the commutator, all of which are placed on the upper side. The regulation is effected by moving the third brush automatically by the governor, and the movement of this brush maintains the speed constant by the varying the counter E.M.F. of the armature. The governor is of decidedly novel construction, rendering it possible to obtain a very good centrifugal force and governing power in small and compact shape. There is no fixed connection between the governor and the regulating brush; nevertheless, the latter is moved automatically by the governor, its centrifugal force being resisted by the tension of two springs provided with means of adjustment, whereby the normal speed of the motor may be controlled at will. These springs, as well as the arrangement by which the governor controls the movement of the regulating brush, are located partly inside the commutator and partly back of it. One of the features of this motor is also that it will reverse the direction of its torque if the speed is increased very slightly above the normal velocity, and with a still further increase the negative torque will rise very quickly. The effect of this upon the regulator is to prevent racing. This property of the machine renders it desirable in running spur-geared elevators, the motor being enabled to hold back with a force nearly as great as its maximum capacity. When the elevator is descending with a full load, it requires about two-thirds as much effort to hold it back as it does to raise the same load, and therefore, unless the descent is resisted by a force nearly equal to this, the velocity of the car would become dangerously great, while the velocity of the armature would run so high as to burst it asunder. Mr. Baxter states that the 10 horse-power motor weighs only 800lb., and runs at the low velocity of 600 revolutions per minute. He also states that he proposes to apply a modification of the same to street railway work, and that he intends to put the motor right into the car wheel, of which it thus becomes an integral part, driving directly on the car axle. This idea, I believe, is not new, but has been worked before, among the experimenters being Mr. Stephen D. Field; but, of course, if an improvement of this kind can be had it is worth securing, and Mr. Baxter's efforts will be watched with interest.

There has been a lively agitation in the gas and electric light fixture industry in this country. Some time last June an organisation was formed in Philadelphia, which has become known by the name of the Gas and Electric Light Fixture Trust, the object of this Trust being to secure co-operation between the manufacturers and the local dealers, so that prices, instead of being cut, might be held up and advanced. Among those who joined it were all the leading fixture concerns connected with electrical work. It has not been all plain sailing, however, for the new combination, as there has been a good deal of dissension in various places, notably at Louisville (Kentucky), and at Philadelphia. One leading manufacturer refused to enter the pool, and it is said that there are already disputes among some of those who are interested.

Pending the decision by the Courts with regard to the incandescent lamp patent suits now pending, Mr. Frank L. Pope, the well-known electrical expert, has occupied himself with compiling a book which he calls "The Evolution of the Incandescent Lamp." This book has been published this week, and has already excited a great deal of interest and attention. Mr. Pope's connection with the Westinghouse Company, which controls the Sawyer-Man, Maxim, and other incandescent lamp patents, is well known, and, as might be expected, the book is chiefly an exposition of the Sawyer-Man side of the case. It is, in fact, practically a synopsis or *résumé* of the evidence that has been presented on the Sawyer-Man side before the Courts, and, as far as can be ascertained, brings up no new matter. As may be supposed, Mr. Edison does not fare any too well at the hands of his doughty opponent. Perhaps when he comes home to meet this attack, after his wonderful reception abroad, he may be inclined to look upon it as the *aliquid amaris* in his cup of happiness at the present time. Mr. Pope takes the ground that the production of any invention is not exactly a spontaneous outburst or creation of an individual mind, but belongs rather to the slow evolution of a long course of discoveries and inventions at the hands of numerous workers. There is something in this theory, and perhaps it will as well suit the invention of the incandescent lamp as any other case.

BRUSSELS NOTES.

(FROM OUR CORRESPONDENT.)

BRUSSELS, *October* 1, 1889.

The tenders for the electric lighting of Brussels, which were sent in on the 1st July, are still under consideration by the Special Committee appointed for this purpose. Amongst the "*soumissionnaires*" is M. Van Rysselberghe, who has presented a somewhat novel project, which has induced the Committee to suspend its investigations into the other schemes until it has been furnished with further details of M. Van Rysselberghe's proposals.

M. Van Rysselberghe, strange to say, is no believer in central stations, but is of opinion that each consumer would prefer to produce his own light, if only the machines for driving the dynamos could be made compact, inexpensive and noiseless, and so as to require no attention. He, therefore, proposes a high-pressure hydraulic service throughout the town; the users of power would then have a suitable agent, and those who wish to have the electric light would have the means of driving their dynamos. As to the street lighting M. Van Rysselberghe proposes small central stations, the dynamos being driven, of course, by water-power. The necessary water would be obtained from the Senne, and M. Van Rysselberghe thinks that the constant cleansing of the city sewers by the used water ought alone to ensure the adoption of his plan, apart from any consideration of its superior economy.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *September* 21, 1889.

Further interesting experiments have been made on the Vienna-Prague trunk line, and all ended very successfully. Speaking over single subscribers' line, Prague to Exchange, Prague Post Office, thence to Vienna Post Office, Vienna Exchange with metallic circuit underground cable to subscribers' station with the same, translators in Prague alone, the result was loud speaking and good articulation, with little noise on the line. With the same circuit, but with translators in Prague and Vienna, the result was loud speaking, good articulation, and still less noise on the line. Another experiment was carried out on the following circuit:—In Prague a subscribers' line 16½ kilometres long, single to Prague Exchange, single line to Post Office, translator then with metallic circuit line to Vienna Post Office, translator there, thence aerial metallic circuit to Vienna Exchange, thence 3 kilometres of cable, one strand earthed, the other continued overhead for 2 kilometres, single line to subscriber. In this case clear and good speaking, with a little noise, was obtained.

Many other experiments were made, all of which were successful, and, on the whole, speaking with two translators was preferable to one in Prague and connection of Vienna metallic circuit cable lines to subscriber without translator. The Landrath translator was used in both cases.

On the 18th instant the line was opened to the public from the call room in Prague Post Office to the Vienna public call room, all these belonging to the State. On October 1st the Exchange subscribers in Prague and Vienna will also be connected. The charges levied by the Government are:—One florin for three minutes' conversation (the call not counted); three florins for express connection, having precedence of the one florin connection.

As regards the Vienna-Budapest line, three metallic circuits are now being run. It is hoped that these lines will be completed by the beginning of October. The charges are to be the same as between Prague and Vienna.

Digitized by Google

The International Electrical Company have recently sent out circulars in which they announce their intention of erecting on the shore of the Danube, in the neighbourhood of Vienna, a large central station for the supply to consumers throughout the city. The station will contain plant of a 100,000-lamp capacity, but at first plant for 20,000 lamps only is to be installed. The alternate-current system will be adopted.

The firm of Ganz and Co. are now engaged in erecting a local installation at a tobacco factory in Budapest. The current is supplied by a direct-current dynamo, supplemented by a battery of 56 Farbacky-Schöneck storage cells. The total number of lamps is 320, partly of 10 and partly of 16 candle-power.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *September* 30, 1889.

A number of comparatively small towns in Sweden have already introduced the electric light, and the town of Laholm is now about to follow their example. The circumstances appear to be exceptionally favourable, a large waterfall being available about 300 yards away, and the necessary sites are obtainable on most reasonable terms.

Lighting of railway carriages by electricity has for about a year been introduced on a small portion of the new Swedish West Coast Railway. The result has been very satisfactory, and this mode of lighting the trains is likely to be adopted on other lines in Sweden. It has now been installed in all the express trains between Helsingborg and Gothenburg, and the latter town and Christiania; also in Finland the electric light has been introduced in the sleeping cars between Helsingfors and St. Petersburg, and in Denmark at least some of the trains between Copenhagen and Korsör are lighted in the same manner.

Some interesting statistics have just been published about the telephone in the service of the Swedish State Telegraphs, which institution employs the former mode of communication to a considerable extent. During the year 1888 the Swedish State Telegraphs laid 1,724 kilometres of telephone lines, the cost amounting to 277,711kr. (kroner=one shilling), to which must be added the money paid for the Gothenburg Telephone Company, viz., 172,640kr., making a total outlay on the part of the State Telegraphs on telephones during last year of 450,352kr. At the close of last year the State Telegraphs possessed altogether 7,218 kilometres of telephone lines, with 3,389 telephones. There were 54 central stations, and 74 telegraph stations had telephonic connection. The number of telegrams and communications despatched at the State Telegraphs through the medium of telephones was as follows:—

Telegrams received through telephone for further despatch	30,967
Telegrams further despatched per telephone	29,306
	60,273
Telephonic communications.....	7,924
Telephonic conversations, at 50 öre (6½d.).....	25,778
Telephonic communications between subscribers	5,146,654

Of private telephone lines (including, of course, those of the various telephone companies) there was a total of 30,676 kilometres, with 302 central stations and 14,234 telephones.

The Corporation of Copenhagen have now decided that they will themselves erect one or two central stations in Copenhagen for electric light. There are two localities where the conditions are very favourable for such stations, better by far than what any town in Germany can boast of. The calculated cost for the first station to be taken in hand is 1,400,000kr., of which 450,000kr. will be absorbed for site and alterations. The number of lamps will be 10,000 incandescent lamps (might be extended to 14,000), and the area will not be beyond a distance of 2,000ft. from the central station. The projected station is intended for indoor lighting, but it is not improbable that the plan may be considerably modified before being realised. It has been argued that the station might with a comparatively small additional cost be increased to a capacity of 20,000 lamps, which would enable the Corporation to use the electric light for the lighting of the large and handsome square, in the immediate proximity of which the first central stations will be located. Voices have also been raised against the Corporation working the electric light themselves, and a fear expressed that they will overcharge and take undue advantage of their monopoly, as many accuse them of doing with their gas works. The calculated annual expenses on the above projected central station are 194,100kr., whereas the gross profits have been put at 274,000kr.

In Stockholm the question of electric lighting seems also to be progressing, and there, too, the gas works seem inclined to take up the matter of electric lighting. The Stockholm Gas Works have been working an experimental station, as it is called, which has given most satisfactory results, and proved the good qualities of the system adopted during last year. There were altogether fixed in Stockholm, by the various electric companies and private electric engineers, 3,832 incandescent and 103 arc lamps, which brought the aggregate at the end of 1888 up to 14,372 incandescent and 247 arc lamps. The electric lamps are 10 per cent. of the number of gas flames, but the consumption of gas has notwithstanding increased with more than 6 per cent. during the year—an experience which tallies with that mode in several other European capitals and large towns.

The Landscrona sugar manufactory, Sweden, has contracted with Mr. Davy Robertson, of Gothenburg, for an electric installation, consisting of eight arc lamps and 220 incandescent lamps.

The town of Holmstad, in Sweden, has also just contracted for a good-sized electric installation with the well-known Stockholm firm of J. E. Eriksson, representatives for Siemens and Halske. The installation comprises a minimum of 1,000 incandescent lamps, and upwards of 80 arc lamps, and has to be completed by July 1st, next year.

CORRESPONDENCE.

THE B. A. COMMITTEE "ON THE MAGNETISATION OF IRON."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have just read a paragraph in your issue of September 27th, in which you comment on the report of the Committee on the "Magnetisation of Iron," read in Section A of the British Association. Permit me to say that the Committee referred to is one for the investigation of certain "Molecular Phenomena associated with the Magnetisation of Iron, Nickel, and Cobalt," and that, as stated at Newcastle, the report of the Committee is deferred till next year, the note presented being merely a brief summary of some of the remarkable phenomena which cluster round the critical temperature at which recalescence occurs in iron and steel.—I am, Sir, &c.,

THE SECRETARY TO THE COMMITTEE.

THE DEFINITION OF IMPEDANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Glazebrook has done a service in pointing out that what is meant by impedance only in particular cases takes the form $\sqrt{\{R^2 + L^2n^2\}}$. This will serve to explain why I have not called this function the impedance, for which you find fault with me in your number for June 21st last. This expression would not represent the impedance, for instance, if there is any mutual induction to be considered.

Of course, it is by a printer's error [No.—ED. *E.*] that the integrals in Mr. Glazebrook's formulation do not appear under the sign of the square root, and I presume it is by a slip of the pen that in the definition the *effective* (and not the impressed) electromotive force is spoken of. Unfortunately this involves the whole question of the expediency of the term.

As long as men dealt merely with steady currents they got on very well with the simple law $\frac{E}{R} = C$, but directly a variable current was employed they found that generally a smaller current was obtained than that represented by the ratio $\frac{E}{R}$. To obtain this when E and R are both known, it will be necessary either to increase R or to diminish E. If the former alternative is adopted the increased R is called impedance. If the latter alternative is adopted, the diminished E is called the effective electromotive force. Why, in the former case, the impedance should not be called effective resistance, not being a member of any Congress, I cannot say. There is just as good reason for giving a single name to the effective electromotive force; from some points of view even better reason. I hasten to air the suggestion, in order that it may *not* be adopted. But I think there is another ground for not using the word impedance. Suppose the conductor to be connected at two points with the plates of a condenser. The current will then be different in the two sections of the conductor. Which are we to choose for the denominator in the formula defining the impedance?

Digitized by Google

In a subaqueous or subterranean cable again the current[2] varies from point to point, and the difficulty is increased indefinitely.—Yours, &c., THOMAS H. BLAKESLEY.

Royal Naval College, Greenwich, Oct. 5, 1889.

[Although our correspondent is, of course, quite right in saying that the integrals should come under the radical sign in the formula in question (see *The Electrician*, Sept. 27th, p. 516), yet the printers are not to blame in the matter. We have commented on Mr. Blakesley's objections to the term impedance in another column.—ED. *E.*]

PROFESSOR ELIHU THOMSON'S EXHIBIT AT THE PARIS EXHIBITION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your description of my exhibit at the Paris Exposition, which appeared in your issue of September 13th, 1889, you refer to the existence of a voltmeter constructed on the electrostatic principle, and close the paragraph by the statement "The instrument closely resembles the electrostatic voltmeter designed by Sir William Thomson." I would say in relation to this that the instrument is nothing more or less than an electrostatic voltmeter, the design of which is due to Sir William Thomson. There is nothing else claimed for it, but in my exhibit it was to be taken in connection with auxiliary apparatus accompanying it, of which your correspondent had evidently not taken notice. The electrostatic voltmeter in question is to be used with a miniature transformer whose primary, of comparatively coarse wire, can be attached to low-potential alternating mains, such as 50-volts secondary mains, the secondary of which transformer is wound with very fine and carefully insulated wire and magnifies the potential 100 times, making it 5,000 volts. The fine wire secondary circuit is then connected to the electrostatic voltmeter of the Sir William Thomson pattern.

The object was to show the possibility of reading low potentials by an electrostatic voltmeter.

For continuous currents the same voltmeter is to be used with a set of condensers charged in multiple at a low voltage, say 100 or thereabouts, and discharged in series by a revolving connection cylinder, so that the potential may likewise be magnified before it is applied to the voltmeter. These two auxiliary devices, the miniature transformer and the set of condensers, were both shown in the exhibit, and ought to be found there in connection with the voltmeter in question.

It may be of interest to your readers to know that the alternating-current motor sketched in Fig. 8 of your article has a single field circuit, and that the armature may be started in either direction, and will increase its speed to nearly synchronising speed if run without load. The machine may then have the load thrown on. An increase of its load tends to diminish the speed somewhat from approximate synchronism. An overload stops the motor. The principle of operation of this motor, I think, is novel. Its action depends on the combined effects of lag of induced current and displaced relation of waves due to translation or rotation of the armature, the initial direction of rotation being that which determines the direction of displacement of waves during their formation, with the effect of setting up a repulsion to the closed armature coil from the field coil which it is leaving, and an attraction for that coil which it is approaching. In other words, the rotatory effort is an effect of magnetic distortion brought about by the combined action of lag of the induced current in the armature coils and the movement of rotation which has been given to the armature initially, and which determines the direction of continuance of such motion.—Yours, &c., ELIHU THOMSON.

Lynn, Massachusetts, Sept. 25, 1889.

THE DEPTFORD CENTRAL STATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It will probably be of interest to your readers to know that during last week current was transmitted from our Grosvenor Station to the Deptford Station with satisfactory results. This transmission of current was made as part of the preliminary work to starting our Deptford Station, from which we shall be supplying current in the course of a few days, a slight delay having been occasioned by the strike at Silvertown, and the consequent non-delivery of a few small parts required for the completion of our machinery.

We are supplied here with electric current from the Grosvenor Station, the E.M.F. of 2,400 volts, at which the current is supplied, being reduced by transformation to 100 volts in the ordinary manner. This current of 100 volts was put into a transformer at our temporary distributing station here, and raised to 2,400 volts, and again into other transformers, raising the E.M.F. to 5,000 volts, at which tension the current was passed through our cables direct to our Deptford Station. There the E.M.F. was successively reduced by transformation to 2,400 volts and to 100 volts, and at this latter working tension our works at Deptford were illuminated.

Doubts have been expressed in many quarters whether we should succeed in transmitting current so great a distance as that between London and Deptford; well, those doubts are now finally dispelled, and the confidence felt by the exponents of the transformer system is fully justified It is also now demonstrated that current can be transmitted without loss of E.M.F., for, notwithstanding five transformations, the E.M.F. of the working tension at Deptford was the same as at these premises.

It may be asked why so many transformations were made. The answer is that we have our transformers constructed for successive reductions from 10,000 volts to 2,400, and finally to 100 volts, and starting, as we were obliged to do, with an E.M.F. of 100 volts, we had to raise and lower the tension in the manner described. I should explain that our system admits of our obtaining a 5,000 or 10,000 volt tension at pleasure by the manner in which we couple our transformers, and that for the purposes of this trial a tension of 5,000 volts was sufficient.—Yours, &c., CHARLES B. WALLER,

Manager and Secretary London Electric Supply Corporation (Limited).

3, Adelphi-terrace, W.C., 9th October, 1889.

[It is scarcely necessary to observe that the proof which our correspondent offers in support of his thesis that "current can be transmitted without loss of E.M.F." would equally well serve to show that "current can be transmitted with an actual gain amounting to thousands of volts." It would merely have been necessary to stop at an earlier stage in the demonstration.—ED. *E.*]

THE STRIKE AT SILVERTOWN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As misleading statements are being circulated with reference to a strike at our Silvertown factory, we ask you to give publicity to the particulars of weekly wages paid by us up to 14th September last, which will be found to compare favourably with those paid for similar work in any part of England:—

	Hours.	Pay.
Labourers (including yardmen and stokers)	63 ...	26s. 3d.
India-rubber departments.....	63½ ...	33s. 7d.
Cable, wire-covering, battery, gutta-percha, electric light, and general departments.....	60 ...	28s. 1d.

No able-bodied labourer employed by us received less than 4¾d. an hour. The above payments do not include those made to foremen, clerks, and skilled mechanics of various classes, who, of course, draw much higher wages.

We employ a considerable number of women and boys, who are not included in the above statement, but who are paid on a scale proportionate to that of the men.

The workpeople are practically in permanent employment, their weekly number not varying much during the year; and our workshops are large and well ventilated and lighted, and our appliances of the best.

Our factory is in the neighbourhood of the docks, and the recent strike there appears to have unsettled the minds of some of the workpeople. The majority of them, however, have been intimidated into leaving their work, having, when going to their meals, to pass through a crowd who hissed and groaned at

Digitized by Google

them and used violent language. In some cases they have been hurt, but will not give evidence lest worse should befall them.

Yesterday about 115 women, who were satisfied with their pay, left work under intimidation, and there are now about 1,600 workpeople thrown out of employment, leaving only 250 still at work.—Yours, &c. WM. J. TYLER, Secretary.

Oct. 4, 1889.

THE HIGGINS' COLUMN PRINTING TELEGRAPH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent, Mr. W. M. Monroe, who in last week's number claims priority of invention for a Column Printing Machine by a Mr. Irish, of which a description was published in 1883, is mistaken in supposing that it was five years earlier than the invention of my Column Printing telegraphic apparatus.

My first patent for a Column Printing Telegraph was granted in the year 1880, and my last patent in the year 1887.

My Column Printing apparatus, which is at present in use at the West-end of London, was constructed, and a description published, before the date of Messrs. Wright and Moore's application for a patent.—Yours, &c., F. HIGGINS.

17 and 18, Cornhill, E.C., October 7, 1889.

THE TESTS OF THE BROOKS' UNDERGROUND SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The test to which I referred in my letter of last week was not intended to represent the conditions which would obtain in an electric light cable. To have made a telephone cable do duty for an electric light cable would have been manifestly absurd, and especially so in this case, as we had a cable laid eminently suitable for electric light purposes, which was tested in the presence of Mr. Ferranti's representative, and which proved to be of a very high insulation resistance.

The test on the telephone cable, with the wires all bunched together, was undertaken as a confirmatory test to the previous ones, showing that not one of the wires was faulty, and that the average insulation was good.—Yours, &c., H. C. HALL.

COMPANIES' MEETINGS & REPORTS.

Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited).

The first general meeting of the above-named Company was held at the Cannon-street Hotel, E.C., on Friday, the 4th day of October, for the purpose of transacting the ordinary business of the Company. Sir John H. Morris, K.C.S.I., Chairman of the Company, presided.

Mr. J. SHURMER, the Secretary, read the notice calling the meeting.

The CHAIRMAN said that before making any particular observations he wished to tell the shareholders that this was a meeting of the Foreign Elmore Company and not a meeting of the original Company. He wished further to call to their notice that it was only a statutory meeting and that their proceedings would therefore be of a somewhat formal nature. There would be no report to be read and no balance-sheet or accounts to submit, but at the same time he might tell them that the public subscription was more than applied for, and that the allotment was made in full, also that the calls had been regularly paid up, and that there were no substantial arrears. Application had also been made for a special settlement and quotation for their shares on the Stock Exchange, and as soon as they had made certain trivial alterations in the Articles of Association—for which a special meeting had been convened that day—they would no doubt obtain what they had asked for. So much for general particulars as to their affairs. The Company had now been in existence for some four months, and the proprietors would doubtless wish to know what had been done so far. He wished to remind them, as stated in the prospectus, that the Company was formed for the purpose of acquiring certain patent rights for foreign countries in the Elmore process, which were enumerated in the prospectus. It was also stated that it was not the intention of the Company to work those patents, but to re-sell such patents by forming subsidiary companies for different countries, and that negotiations had already been commenced for the sale of those patents. Now, the first thing done by the Directors after the formation of the Company was to again go into the different rights and certificates in the foreign countries, as stated in the prospectus, and then the next step was to consider whether they should at once proceed to form the subsidiary companies, and renew and carry on the negotiations that had already been commenced to that end, or whether they should wait for the successful completion of the Elmore processes in England and the demonstration to the general public of the capabilities of the invention. They went fully into the matter, and they found that in the case of almost every proposal and application which

Digitized by Google

had been made to them the people required various tests and experiments to be conducted before they would be satisfied to complete their negotiations and conclude the terms. The effect of such a state of things was naturally to very greatly reduce the estimated money value of the patents if they had sold them then, and they felt, therefore, that the wise thing to do was to wait until the success of the home Company had proved the commercial value of the process to the satisfaction of the public. They felt that it was only then that they would get the full value of their patents, and they decided therefore, after full consideration, that they would not for the present at all events renew the negotiations or receive any proposals whatsoever unless they were of a more definite character. They replied to a gentleman, who wished to continue negotiations with them, as follows :—

"Sir: I am directed to acknowledge the receipt of your letter, and to say in reply thereto that until the Company is in a position to fully satisfy the public generally in regard to the commercial value of the Elmore process my Board must refrain from committing themselves to any proposals in the matter for the sale of all or any of our patents, or to enter upon any exclusive negotiations to that end. At the same time, any specific and definite offer made to this Company for the whole or any of the patent rights would have the careful consideration of the Directors."

He (the Chairman) trusted that the shareholders would approve of the action of the Directors in the matter. He need scarcely tell them that had they proceeded to reopen negotiations on the terms already mentioned they would have been offered a very much smaller amount for their patents than they had every reason to hope and believe they would receive when the patents had been proved and the processes were at work in England. As they said in the letter that he had just read, they were perfectly prepared to receive and to carefully consider any specific and definite offer that might be made to them. As the shareholders would readily understand, no definite offer whatever was made to them; the people did not want to make definite offers, but in fact, in his opinion, to enter into negotiations with them, and to get them into such a position that they would be very much prejudiced and compelled to accept terms very much lower than they would receive if they waited until the development of the works of the English Company was carried out successfully. When he said carried out successfully, he did not mean to convey that the Directors of this Company had any doubt whatever as to the ultimate success of the concern, but they had to prove this to the satisfaction of the public, and to show that the results were really being believed in England. It would be perhaps recollected by some of them that when the meeting of the original Elmore Company was held it was announced that a series of experiments were being conducted in Paris, and that these experiments were only on a very small scale. Now, in order to be entirely satisfied in the matter, and to satisfy the public, works of the home Company were in course of erection for working the process on an extensive scale, and they had every reason to believe that the results would be most successful, and would qualify them to renew negotiations and to carry them out successfully. There was one point upon which the shareholders would, of course, be anxious to have information, viz., when it was likely that they would be in a position to carry out the process to the full satisfaction of the public. Well, when this Company was first formed they had every reason to hope and believe that by the present time they would have been in the position to which he had referred, of seeing the successful completion of the Elmore processes carried out to the satisfaction of the public and all concerned. A few weeks after the formation of the Company, the erection of the buildings necessary for the plant was begun, but the work was soon stopped in consequence of a strike amongst the workmen engaged thereon. The matter in dispute, which was the cause of the strike, was a very trivial one—at least it appeared so to the board—it being only the question of an increase of one-halfpenny per hour in the salary or pay of the bricklayers' workmen. So impressed were the Directors of the Elmore Company of the absolute necessity of preventing any possible delay, and of pushing on the works to the utmost extent in their power, that they offered themselves to make up to the contractors the difference, provided they agreed to the terms that were demanded by the workmen. Unfortunately, the contractors would not agree to it, and as there was in the contract the regular strike clause the Company were unable to claim any damages from the contractors. The result was that there was a delay of from six weeks to two months, but he was now very glad to be able to inform them that some weeks since the work was recommenced and was now going on most satisfactorily, and they had every reason to hope that in the course of a few weeks the buildings would be erected and the whole of the Elmore processes completed and carried out to the full satisfaction of the public, and they would have demonstrated to them the great commercial value of their process. Of course, as soon as this was done the Directors would be in a position to renew negotiations for the forming of subsidiary companies, and the value of the patents having thus been fully demonstrated, they would be able to obtain considerably enhanced terms to what would have been the case before. Continuing, he said that there was only one other point to which he had to refer, which was that they had received applications or proposals from some eight or nine different parties for the renewal of negotiations for different foreign countries, namely, France, Belgium, Italy, Switzerland, Spain, Germany, Canada, United States and Sweden. He had little doubt that as soon as the results of the home Company were known they would receive many more applications than those that they had already received. He believed that that was all he had to say, but if there was any particular point that he had omitted to refer to, or any question that any gentleman would like to ask, he or one of his colleagues would be glad to answer it, and to give the best information in their power. He had, as he had said, no resolution to propose.

No questions being asked by any shareholder,

The CHAIRMAN said that it appeared they were all satisfied with his statement, and they would therefore consider the business for the statutory meeting as over, and they would now proceed to the work that they had to transact at the special meeting. Accordingly an extraordinary general meeting of the shareholders was then held in order that the subjoined resolution—rendered necessary in order to comply with the requirements of the Stock Exchange before that body would give the Company a special settlement and official quotation of its shares—might be proposed, namely :—

That the following Clauses of the Articles of Association of this Company be and the same are hereby altered, revised, added to, repealed and (or) cancelled, as follows :—

"*By striking out of the second paragraph of Article 24 the words, 'on any bill or note or contract remaining unperformed.'*

"*By striking out of the second line of Article 60 the words 'one-fifth,' and substituting therefor the words 'one-tenth.'*

"*By striking out of Article 71 the words 'hereafter to be elected.'*

"*By striking out entirely Article 82.*

"*By adding to Article 105, after the words 'such securities as they may select,' the following words, 'subject always to Article 36.'*"

Mr. J. SHURMER, the Secretary, read the notice.

The SOLICITOR of the Company, Mr. Hays (Newman, Hays and Co.), explained the object of the alterations, and read the amended articles.

The CHAIRMAN then proposed the resolutions *seriatim*.

Mr. HOLLAND seconded them, and they were all carried.

The SOLICITOR said, that to be perfectly legal they must also be carried *en bloc*.

The CHAIRMAN moved the approval of them *en bloc*.

Mr. HOLLAND seconded.

The motion was carried.

The CHAIRMAN said that it would be needful to hold another meeting to confirm the resolutions that had been passed, so as to render them

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN

special resolutions; the shareholders would receive a notice in a few days time, and the meeting would, being a purely formal matter, take place at the Company's offices in Bucklersbury.

A vote of thanks to the Chairman closed the meeting.

Anglo-American Brush Electric Light Corporation, Limited (in voluntary liquidation).

A meeting of the shareholders in this Corporation was held at the offices, 112, Belvedere-road, on Thursday, "to settle the list of contributories." Mr. E. Garcke, one of the liquidators, presided.

The CHAIRMAN said: I have to thank you, gentlemen, for attending the meeting, but the business is purely formal. It is simply to settle the list of shareholders who are contributories, and to enable us to prepare and issue the new certificates of the new Company—the Brush Electrical Engineering Company (Limited). I may take this opportunity of stating that the business of the new Company is proceeding very satisfactorily. We are exceedingly busy with current orders, and the arrangements have been completed for taking over the new works at Loughborough of the Falcon Company. We are very busy there. I may say that those works are fully occupied at present with orders from the new Company, so that they are almost independent of their old customers. I shall be happy to answer any question that any shareholder may put to me, but unless any objections are raised by any shareholders, the list which I have prepared will be settled, and the new certificates will be made out by the new Company in accordance with this list. The shareholders have all had notice of their holdings as settled in this list. The meeting has been called in accordance with the Companies Acts, so as to give shareholders an opportunity of objecting if they see fit.

Mr. WM. ASH said he had been connected with five or six other electric light companies, some of which had disappeared entirely, involving him in considerable loss. He hoped that this Company would be an exception in that respect. What was meant by par value?

The CHAIRMAN: That means the nominal value of the shares. The nomiual value of the Old Shares is £5, and of the New £2 for the Preference and £3 for the Ordinary Shares. You will receive one Preference Share of £2 and one Ordinary Share of £3 in the New Company in exchange for one Old Share of £5. As there are no other questions I may take this list to be settled.

The proceedings then terminated.

NEW COMPANIES REGISTERED.

THE ECONOMIC GOLD EXTRACTION COMPANY (LIMITED).—Registered by Slade and Munk, St. Clement's House, Clement's-lane, E.C., with a capital of £175,000 in £1 shares. Object, to adopt an agreement, dated May 6, made between C. E. Mildenhall and H. M. Collins as trustee for the company; to acquire the patent rights and property referred to in such agreement, and to continue the business therein mentioned; to enter into agreements or contracts to purchase, deal in and with mineral, chemical, and electrical properties and inventions of every kind on such conditions as the directors may deem expedient. There shall not be less than three nor more than seven directors, the first to be appointed by the subscribers to the memorandum of association. Qualification, £100; remuneration, £1,300 divisible, and 5 per cent. out of net profits after 10 per cent. dividend.

THE MAQUAY SYNDICATE (LIMITED).—Registered by Johnson, Budd and Johnson, 24, Austinfriars, E.C., with a capital of £12,000 in £100 shares. Object, to acquire or enter into arrangements for the option of purchasing the benefit of the inventions for an improved voltaic battery for improved means for feeding electric batteries and for removing the plates therefrom, and for a miner's lamp, respectively protected by letters patent, No. 15,040 of 1885, No. 990 of 1887, and No. 14,932 of 1888.

NEW SPANISH ELECTRICAL COMPANY.—The *Dia* of October 5 announces the formation of a new company in Bilbao under the title of "La Electra," with the object of supplying the electric light to the public. The chairman of the company is D. Manuel de Ayarragaray, vice-chairman D. Ramon Bergé, and the other members of the Board Signors Eduardo de Achutegui, Luiz de Zubiria, and Jose A. de Ibarra. The managing director is D. Valentin de Gorbéna.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The accounts of this company, subject to audit, show a profit sufficient to enable the directors to recommend a final dividend of 1s. per share, making, with previous distributions, a total dividend of 6 per cent. for the year ended 30th June, 1889, and also the payment of a bonus of 3s. per share, both free of income tax, which together will amount to £26,000, being a distribution in the aggregate of 7½ per cent. for the past year, leaving a balance of £47,609. 3s. 9d., of which amount £45,000 has been placed to the reserve fund, increasing that fund to £259,660. 9s. 8d., and £2,609. 3s. 9d. carried forward. The above dividend and bonus will be payable on the 7th November next. The receipts of this company for the week ended October 4, 1889, amounted to £2,936.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of September, 1889, amounted to £2,139, as compared with £1,888 last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—This company announce the payment by warrants on the 1st of November next of interest for the half-year ended October 31st on their Four per Cent. Mortgage Debenture Stock. The books will be closed from the 27th October to 1st November both days inclusive. The traffic receipts of this company for the month of September, 1889, amounted to £51,881, and to £49,273 in the corresponding period of 1888.

GLOBE TELEGRAPH COMPANY.—This company has declared an interim dividend of 3s. per share on the Preference Shares, less income-tax, and of 2s. per share on the Ordinary Shares, income-tax having already been deducted.

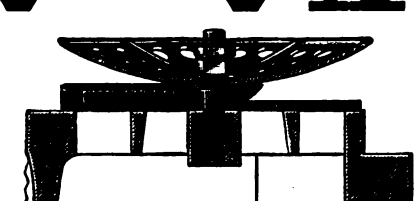
GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company for the month of September, 1889, amounted to £25,000. From the 1st January to 30th September, 1889, they were £203,200, against, in the corresponding months of 1888 and 1887, £202,600 and £197,720 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended October 4, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £1,604.

THE ELECTRICITY SUPPLY COMPANY FOR SPAIN (LIMITED).—Subscriptions were invited this week for a capital of £100,000, in 19,900 Ordinary shares of £5 each and 100 Founders' Shares of £5 each in the above undertaking. The directors of the company are the Right Hon. Lord Castletown of Upper Ossory, chairman, Sir Henry Cartwright, Knt., 1, Courtfield-gardens, South Kensington, S.W., Robert A. Germaine, Esq., M.A., L.C.C., 21, Philbeach-gardens, South Kensington, S.W., Alfred G. Gillingham, Esq., George-road, Sutton, Surrey. The managing director is Exmo. Señor Don Pedro Pastor y Landero, Madrid. The engineer is F. C. Phillips, Esq., Assoc.M.Inst.C.E., M.Inst.E.E., and the secretary *(pro tem.)* is Philip Arderne Latham, Esq. The company is (the prospectus states) formed for the purpose of erecting a central electricity supply station in Madrid, under a concession recently obtained from the authorities there, for the purpose of generating electricity on a large and economical scale, and distributing it by means of underground mains to premises requiring electric lighting or motive power. The concession is unlimited in duration. The company does not intend to confine its attention to Madrid, but contemplates extending its operations to other important towns in Spain. The company is bound to no particular system, and in the prosecution of its business will be free to adopt the best means available from time to time for the generation and distribution of the electric current. Messrs. Hammond and Co. have contracted to erect a central station in Madrid for the company. It may be worth mentioning that the price of gas in Madrid is over 9s. per 1,000 cubic feet. The offices of the company are situate at 15, St. Helen's-place, E.C., and at 13, Goya, Madrid. The list of applications for shares closed yesterday at 4 p.m.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 596.—Vol. XXIII. FRIDAY, OCTOBER 18, 1889. Price Fourpence.

NOTES.

A Reuter's telegram from New York announces that in the action brought by the Westinghouse Company to restrain the Edison Lamp Company from infringing the Sawyer-Mann patents, judgment has been delivered in favour of Edison. The case seems to have turned not on the flashing process, but on the Sawyer-Mann claim for the use of a "fibrous or textile substance" for incandescent lamp filaments. We shall no doubt receive full particulars from our New York correspondent within a few days.

We reprint from the New York *Electrical World* an able article by Dr. Louis Bell "On the Present State of Traction by Storage Batteries." This is a question which affects us even more closely than it does our American cousins, seeing that perhaps as much as 75 per cent. of our tram lines cannot be worked electrically by any other method at present in the field. It is well that this fact should be fully recognised. Such systems as the "Series" and the "Lineff" are well adapted in themselves for suburban traffic, and either of them would probably add perceptibly to the dividends of many such lines. But, unhappily, even here a vested interest of the most powerful and ubiquitous character challenges their intrusion. We refer to the cyclists, and it is impossible not to sympathise with their aversion to the "slot."

Returning to Dr. Bell's Paper, we find that he estimates the efficiency of battery traction from the indicated horse-power of the engine to the power delivered on the wheel axle at 40 per cent. We do not think that this can be considered an unfair estimate. For direct working with overhead lines Dr. Bell allows no more than 50 per cent. efficiency. There is, however, another point to be considered before direct comparison can be made—How much of the work done by the batteries is uselessly expended in dragging their own weight? To make the comparison quite fair Dr. Bell takes the "economic coefficient" of each system, which is obtained by multiplying the commercial efficiency by the ratio useful weight/total weight of the car and its equipment. This gives the value 38·5 per cent. for the direct system, and only 18 per cent. for the batteries. What we need (we wish there were some better prospect of getting it) is a far lighter cell, and one capable of withstanding the disintegrating effects of continuous changes of current density. In this direction progress has been very, very slow. Recently we hear hopeful accounts of a cell which is, we believe, now being tried in actual work by the Electric Traction Company. This company has had a long and somewhat trying experience, and may certainly be trusted to know what is wanted in a traction cell.

In view of such considerations as these, we really have very little patience with the persons whose "system" consists in having two motors on each car, to be used one at a time, or in putting the cells in a separate trolley. There *may* be, probably there is, something to be said for the latter suggestion, but in the former, regarded as an "invention" and a "system," we have never been able to perceive the merit. If we can only get a really efficient battery, we need not worry much about the motors.

We have received a card of invitation from the Executive Committee of the Magnetic and Hypnotic Society of Great Britain to be present at an experimental lecture by *Professor* Milo de Meyer on "Practical Magnetism and Hypnotism." So far as we can judge from the list of Council, this Society appears to be fathered by men of good standing. We must, however, emphatically protest against the use, or rather misuse, of the word magnetism. Nothing in the nature of scientific proof has up to the present been brought forward establishing a connection between magnetism and physiological phenomena. Meanwhile, the employment of the term in this relation is a source of profit to the quacks. We feel all the more entitled to make this protest since we observe in the pamphlet sent us by the Society that they are great sticklers for the proper use of the term hypnotism.

The Edinburgh Exhibition in which, as our readers are already aware, it is intended to make a special feature of electricity, is passing through the preliminary stages of its existence in a highly satisfactory manner. A goodly array of patrons has been obtained, and an able and energetic executive committee has been chosen. An excellent site, easy of access, and of ample dimensions, has been selected at Merchiston. The guarantee fund has already reached the required sum of £20,000, and arrangements have been made for the transfer to Edinburgh of several important exhibits now installed at the Paris Exhibition. A good idea may be formed of the suitability of the proposed site when we mention that it is bounded on the north by the Caledonian main line, while the suburban railway of the North British Company intersects the grounds. On the south is the Union Canal, providing a ready water supply and the means for a fine display of electric launches. We trust an ex-

Digitized by Google

hibition which promises so well will not be allowed to degenerate into an *omnium gatherum* devoid of special interest, and in which the lighter entertainments encroach unduly upon the heavier.

M. HOSPITALIER, who is a well-known purist in matters of definition and terminology, has just achieved a triumph in connection with the International Congress of Applied Mechanics, which sat last week in Paris. In the course of the proceedings a discussion took place on the practical unit of power, and it was decided to retain the *cheval-vapeur*. M. HOSPITALIER liked this but little, but what vexed his righteous soul far more was the flagrant misuse of the terms "force," "energy," "work," and "power," in which it seems nearly all the speakers indulged. By his influence a Committee was at once appointed to define, on behalf of the Mechanical Engineers, the precise signification of these terms. We do not greatly admire the mode of definition which has been chosen. The definition of Force is quite unscientific, whilst Work is defined with scholastic precision.

1. The word FORCE is to be employed only as a synonym of the word EFFORT, as to the exact signification of which there is no dispute.

2. The word WORK designates the product of a force by the path described by its point of application following its own proper direction.

3. The word POWER shall be exclusively employed to designate the quotient of a [given amount of] work by the time required to perform it.

BUT perhaps the most interesting feature is the recommendation of the Committee (afterwards endorsed by the Congress) to adopt the PONCELET as an alternative unit to the horse-power. The PONCELET is equal to 100 kilogrammetres per second, and it therefore follows that—

1 Poncelet = 0·981 kilowatt.

1 Kilowatt = 1·0193 poncelet.

It remains to be seen whether this permissive legislation will or will not remain a dead letter, but on this side of the Channel it is probably safe to prophesy that it will.

FROM the annual report of the POSTMASTER-GENERAL of Queensland we learn that the Telegraph Service of that colony has suffered severely through the prevailing drought of last year, and the consequent frequency of bush fires. Against these outbreaks the adoption of iron poles appears to be little or no protection, the lines being destroyed in many cases for several miles at a stretch. The wires are often fused into short lengths, and insulators broken through the poles becoming red hot. As, however, the iron poles maintain their ground they are decidedly superior to wooden ones, especially in a country like Queensland, where timber is sometimes very scarce; and the old wooden poles are now being rapidly displaced by iron.

THE course of lectures on electro-physiology and therapeutics which are now being delivered with marked success at the Institute of Medical Electricity by Dr. ARTHUR HARRIES and Mr. NEWMAN LAWRENCE is another instance of the good work which is being done by this institution in lifting medical electricity out of the region of empiricism and quackery. There are few more promising fields than that of electro-therapeutics, and we are not surprised to learn that these lectures are being well attended by medical men, many of whom have expressed the opinion that this course is just the thing wanted by those members of the profession who have not had the opportunity of making a special study of this important subject.

WHEN a man writes and publishes a book in this country he is not necessarily held to have performed a meritorious deed. On the contrary, he thereby presents himself as a suitor at the bar of Public Opinion (competent opinion, of course, if the volume be of a technical character), and unless his work can pass a careful and candid examination, the Author does not usually get off scot free. If he be adjuged guilty of adding to our groaning shelves a weak, or worthless, or inaccurate book, or even a merely unnecessary book, he suffers at the hands of the Reviewers the penalty of his crime. It is not so in America; in that great and free country, he whose name figures on the title page of a "scientific" treatise is accounted thereby a worthier man. Whether the book be good, bad, or indifferent, the reviews (with the rarest exception) are short and sweet; and the Author has only to swallow down the honeyed meed of praise. This, of course, fully accounts for the peculiar state of mind of an American correspondent whose letter will be found in another column. It is interesting to learn that the style of the book in question (confessedly adapted to infants of tender years) "has been to many of its older readers its great charm." We, too, were moved thereby, but we fear that our laughter was touched with a dash of cynicism. However, for those who like to take their "science" couched in the style and, as far as possible, in the language of the nursery, the "A B C of Electricity" will doubtless prove a charming work.

A CORRESPONDENT writes:—"There is a village not far from London which has recently been promised the blessing of the electric light. The district being a scattered one, overhead wires are to be used, and as a preliminary, several of the roads are now beautified(?) with 30ft. green wooden poles. Last week there was an indignation meeting touching those poles, at which one speaker, a decidedly small man, strongly protested against the statement that it would make the roads safer. His house, he said, was some half-mile from the station, the road lonely, and a policeman never seen at night. Now at present, he said, if he wore good big boots, who was to know by sound that he was not six foot two, and broad in proportion? When that road is brilliantly lit up, however, a tramp would not only see his real size, but also that there was no one else near, and finish him off without the slightest danger of being caught. No—the electric light would really be *very* dangerous at night."

WE are glad to be able to contradict the rumour current a few days ago that Mr. ALBION T. SNELL, of the firm of Immisch and Co., had met with a fatal accident in a North of England coal mine. The unfortunate gentleman who was actually killed under these circumstances, and who bore a similar name, was in no way related to Mr. A. T. SNELL.

Digitized by Google

Aberdeen.—The Town Council has decided to apply for an electric lighting Provisional Order.

Hawick.—The Hawick Gas Company has asked the consent of the Town Council to its applying for electric light powers.

Dover.—A special committee of the Town Council has been appointed to consider and report upon the question of electric lighting.

Partick.—The report of the special committee of the Partick Board have advised the Board to decline to give their consent to any application for a Provisional Order.

Middleton.—The Middleton (Lancs.) Town Council has decided to oppose the application of the Municipal Electric Light and Power Corporation, for a Provisional Order.

Burslem.—It was resolved at the last meeting of the Town Council that application should be made for a Provisional Order to authorise the Council to supply the electric light.

Hastings.—A meeting of the Town Council is called for the 29th inst. to authorise an application by the Council for an electric-lighting Provisional Order for public purposes only.

Paris Exhibition Awards.—The Silver Medal obtained by Mr. Samuel Elliott, of Newbury, at the Paris Exhibition was awarded to him for wood-mouldings and electric wire casings.

Trade Catalogue.—Messrs. Winfields (Limited), of Cambridge-street, Birmingham, announce the issue of a comprehensive catalogue of new and original designs in Electric Light Fittings.

The Lighting of the City.—The special meeting of the Commissioners of Sewers to consider the proposals for lighting the City by electricity, announced for Tuesday last, will be held on Monday next.

Weston-super-Mare.—At the last meeting of the Board of Commissioners, the consent of the Board to the application by the Laing, Wharton, and Down Construction Syndicate for a Provisional Order was refused.

Conisboro'.—The inhabitants of Conisboro' are at present considering the question of the lighting their streets, and a section of the residents advocate making arrangements with an electric lighting company.

Bremen.—A Commercial and Industrial Exhibition for the north-west of Germany will be opened in Bremen in 1890. The section for gas, steam, and electric motors, as well as for tools and machines, will be international.

Govan.—The Govan Commissioners, after considering the report of the committee appointed in July last, have resolved not to make application for electric lighting powers, or to give their consent to any company applying for powers.

Canton.—A Chinese Electric Light Company has been formed to light the city of Canton, with a capital of $400,000. It will be the first electric light plant ever placed in China. The machinery is to be purchased in the United States.

The Old Students' Dinner.—The fifth annual dinner of the old students of the City and Guilds Institute was held on Saturday last at the Manchester Hotel, Aldersgate Street. The number of those present was larger than usual, and the festivities were as successful as ever.

Electrical Engineering Appointment.—A statement appeared in our issue of October 4th, to the effect that Mr. Herbert E. Starr had been appointed to the Central Electric Lighting Station at Exeter. We are requested, however, to state that the appointment is only that of articled pupil.

Appointment Vacant.—The Electrical and Lighting Committee of the forthcoming Edinburgh Exhibition are advertising for an electrician to the Exhibition. The salary offered is £300 for the period from December 1st, 1889, to November 30th, 1890. Further particulars will be found in our advertisement pages.

Harrogate.—At a special meeting of the Town Council, held on Monday, the notices from the Laing, Wharton and Down Construction Syndicate, the Electric Construction and Maintenance Company, and the National Electric Supply Company were taken into consideration. A sub-committee was formed to deal with the question.

Sad Result of the Delay on the Spanish Land Lines.—A terrible illustration of the delays so common in the Spanish telegraph service has recently been afforded by the execution of a man at Ossuna, in Andalusia, whose reprieve was delayed on the wires, and only arrived at its destination after the sentence had been carried out.

L'Ingénieur-Conseil.—Our Belgian contemporary *l'Ingénieur-Conseil*, which has hitherto appeared fortnightly, has celebrated the twelfth year of its existence by commencing a weekly issue. The journal has also been considerably enlarged, and a comprehensive series of articles on the machinery and dynamos at the Paris Exhibition is announced.

Burglary at Messrs. Woodhouse and Rawson.—Two men were charged last week with breaking and entering the premises of Messrs. Woodhouse and Rawson, at 12, Sise-lane. The basement window was broken, and near the prisoners when they were arrested were found four gravity ammeters and 73 incandescent lamp globes. The prisoners were remanded.

Tenders Wanted.—The South Hornsey Local Board invite tenders for the construction and maintenance, for a period of seven years, of street fire-alarm posts, and connecting the same electrically with the fire station in Milton-road, South Hornsey. Tenders are to be sent in not later than the 12th November. Further particulars will be found in our advertisement pages.

House Lighting.—The mansion of Scatwell, situated on the banks of the river Conon, about ten miles from the Muir of Ord Railway Station, and belonging to Mr. W. G. Bell, has just been fitted with the electric light by Mr. R. F. Yorke. The current is supplied to a battery of accumulators by a dynamo situated about 200 yards from the house and driven by a turbine.

Portsmouth.—On the 18th inst., says the *Southampton Times*, the Roads and Works Committee of the Portsmouth Corporation will consider the notices of applications for licenses for the supply of the electric light in the borough. It is generally anticipated that the application of the Portsmouth and South Hants Electric Supply Company will be the one supported by the Corporation.

Luton.—At the last meeting of the Town Council a letter was read from the Municipal Electric Light and Power Corporation asking for permission to supply electric light to the borough. The application was referred to the Highways and Lighting Committee for consideration and report. The Midland House-to-House Electricity Company have already applied for the consent of the local authority.

Pontypridd.—At the last monthly meeting of the Local Board a letter was read from the solicitor of the Pontypridd Electric Lighting Company urging that the company ought to be given the power to run the wires overhead, the provisions of the Board of Trade being ample for the protection of the cable. It was unanimously decided to adhere to the previous resolution that in the town the wires should be laid underground.

The Electric Subway Railway Scheme.—The scheme for an electric subway railway, which was thrown out by a Committee of the House of Commons last year, is to be reintroduced in the coming Session, and an effort will be made to combine it with the new thoroughfare decided on by the County Council. The Council took exception to the railway last year, and it is hoped that they may take a different view if the scheme is brought forward again.

The Edinburgh Exhibition.—A meeting of the Executive Council was held on Friday. It was reported that, with the £500 voted by the Glasgow Corporation, the guarantee fund had reached the figure originally aimed at, viz., £20,000. It was agreed, however, to keep the fund open some time longer. It is anticipated that the Exhibition will be opened early next May. Sir Henry Isaacs, the Lord Mayor-elect, has accepted the office of President of the London Committee of the Exhibition.

Electrical Engineering Cards.—These are handy little pocket cards which are being issued weekly by the General Electric Company, and they contain a considerable amount of useful information in a small compass. Of the first three cards published, one gives Mr. Preece's Fuse Tables, and the other two give respectively in a compact form the prices and other necessary particulars of electric light casings and "Apostle" carbons. The General Electric Company will be glad to send these cards to anyone in the trade.

Digitized by Google

Accumulators at the Paris Exhibition.—In addition to the silver medal awarded to the Electrical Power Storage Company for its system of distribution by means of accumulators, the following awards were made by the jury of the Paris Exhibition to makers of secondary batteries:—Grand Prize: M. Gaston Planté. Gold Medal: The Société l'Électrique of Brussels, who own the Julien patents. Silver Medal: The Société Française des Accumulateurs (Philippart Frères), who own the Faure-Sellon-Volkmar patents for France; M. Gadot, M. Émile Regnier.

Electric Lighting at Pontardawe.—Messrs. Paterson and Cooper have recently fitted up a very complete installation for Mr. Arthur Gilbertson, of Pontardawe. The plant comprises a 16 horse-power nominal engine, a locomotive boiler working at 90lbs. pressure, and two "Phœnix" dynamos belted direct to the engine. One 120-light machine supplies current to All Saints' Church and to Mr. Gilbertson's residence, Glamloyd, nearly a mile distant. The other machine, a 300 lighter, supplies current to the tinworks, which are lit by arc and incandescent lamps.

London County Council.—At the last meeting of the Council the Highways Committee reported that the Council on the 1st instant signified its disapproval of the works referred to in two notices given by the Kensington and Knightsbridge Electric Lighting Company. The principal cause of objection had now been removed, as with the present amended notice the company had sent in plans showing that the sizes of the straining-up and service boxes to be used had been considerably reduced. The committee recommended that the Council should give its consent to the works referred to.

Telegraphic Communication with Mauritius.—Considering the importance of the trade of Mauritius, it is curious, says the *Financial Times*, that the island is still without telegraphic communication with the rest of the world, although the extension of the African cable to the place has been talked about for years past. The owners of such a line would net quite a good income by conveying information respecting the disabled vessels which are constantly seeking a refuge in Mauritius. It would almost pay the underwriters at Lloyd's to connect the island with the mainland out of their own pockets.

The Sellmann Electric Signal for Ships.—A new signal light, the invention of Lieutenant Sellmann, of the German Navy, was tried at Devonport last week. This method is a combination of three electric lights. A number of messages were exchanged between the Seamen's Barracks and H.M.S. "Defiance," and the experiments were watched by the Naval Commander-in-Chief, Admiral Sir W. Dowell, K.C.B. As a result of the experiments, Lieutenant Sellmann's invention is very highly spoken of, but those competent to judge assert that the present lamp in vogue in the navy, the Colomb lamp, has many and decided advantages over it.

Tenders Wanted.—The Municipal Commissioner for the city of Bombay will be prepared to receive tenders, on the 9th January, 1890, for the experimental lighting by electricity of the main road from the Crawford Markets to the end of the Apollo Bunder. Firms willing to undertake the experiment (for which no longer period than two years will be guaranteed) are asked to submit full particulars as to the system or systems which they may propose to adopt either wholly or in part, the number and position of lamps to be erected, the illuminating power, and the rates to be charged monthly. Further particulars will be found in our advertisement pages.

Copper.—The September copper statistics are less favourable than those for previous months, the reduction in the visible stocks during the month being infinitesimal. The deliveries aggregated only 9,436 tons, against 13,923 tons in August, and as the receipts during September were 9,120 tons, the stock was only reduced by 316 tons, leaving it on the 1st of October 105,669 tons. So far, the price of copper has been maintained at a price in excess of that which obtained when the stocks of that metal were less than one-half of their present weight, but the diminution in consumption, if continued simultaneously with the present large output, cannot fail to compel a considerably lower range of prices.

The Electric Light at the Exeter Theatre.—The Theatre Royal was opened last week. The house is almost entirely lighted by electricity, very little gas being used, and none whatever on the stage. The current is supplied by the Exeter Electric Light Company from their works, situate in the New North-road, about 250 yards from the theatre. The stage is lighted by means of batten, side and proscenium lights, there being in all six adjustable battens, each carrying 40 16 candle-power lamps, with fusible cut outs attached to the ends of each batten, the lamps being protected by a light wire frame fixed to batten. The side-lighting is effectually supplied from 10 lamps, arranged in a vertical row on each side of the stage. A row of 50 lamps supply the front or proscenium lighting. The flys are lighted by 8 single lamps, secured to the walls on either side by neat brass brackets. The auditorium is now lighted by 20 lamps, suspended from the dome, but these are to be replaced by a 50-light electrolier. Other lights are placed in different parts of the house, the total number of lamps used throughout being about 500.

St. James's Vestry.—At the last meeting of this Vestry the Lighting Committee recommended "that the London Electric Supply Corporation should be informed, with reference to their notice of intention to lay mains in certain streets, that the Vestry have no desire to oppose the commencement of operations on technical grounds, but that, before approving any plan or giving consent to any such work, they feel it their duty to ascertain that the preliminary obligations of the Provisional Order have been complied with, and would therefore be glad of information as to whether the Corporation have yet satisfied the the Board of Trade, and are in a position to fully and efficiently discharge the duties and obligations imposed upon them by the Order; whether they have yet deposited or secured the sum prescribed by the seventh section, and what steps they have taken in the matter of providing a second generating station." The Clerk read a letter from the Board of Trade stating that they were still in communication with the company on the subject; and one from the company stating that the negotiations would be settled in the course of a few days. It was moved that the whole matter be referred back to the Committee, to obtain further particulars regarding the company's position. The motion was carried.

Messrs. Woodhouse and Rawson's New Wiring Tables.—In compiling and publishing the set of Wiring Tables which have just been issued by Messrs. Woodhouse and Rawson we do not hesitate to say that this firm has conferred a distinct boon upon the electrical community. The preparation of Tables of this character must always be to a certain extent an affair of compromise; the problem to be solved is that of conveying the fullest and most accurate information in the most readily available form, and in small compass. In these Tables we are of opinion that this end has been more fully obtained than ever before. The following are the questions to which the Tables are intended to furnish an answer:—

1. To find by inspection the cable to use for a given current and current density, with a fall of potential of 2 volts.
2. To find the correct cable to use for a given current, with a given current density and a fall of potential of N volts.
3. To find the correct cable to use for a given length and current, allowing a fall of 2 volts.
4. To find the current density when any cable is employed for a given current.

In addition the Tables give the number of 50-volt and 60-volt lamps corresponding to the given current, the necessary correction (furnished by Mr. Mordey) for alternating currents of given frequency, and they show by larger type the current for each cable which corresponds to a density of 1,000 amperes.

The Cousens' Electrical Process for Extracting Gold.—On the occasion of a recent visit of a party of gentlemen interested in gold mining to the works of Messrs. R. Hornsby and Sons, of Grantham, the Cousens' electrical process for extracting gold was inspected. The ore, after being crushed by the stamp battery, passes through metallic rollers, which catch up any iron substances that may be in the ore or quartz, and proceeds into a large barrel strengthened by iron bands. Some inexpensive chemicals are introduced into the barrel along with the pulp, and the barrel rotates whilst a current of electricity is passed through it and the ore. In about an hour's time the pulp is released, and flows into a large pan having rotatory fingers, and afterwards

Digitized by Google

proceeds in the ordinary way through riffles on to the plates. From the pan the pulp flows over amalgamated plates, and subsequently over blanket strakes, the plates being kept clean by rubbers, supplemented by electrical activity. The rubbers are carried by endless chains, and, while these are connected to the positive pole, the plates are connected to the negative pole of a dynamo or battery. The process was put to a severe test as the ore which was passed through was almost entirely pyrites, and practically free from quartz. Mr. Cousens' process is considered by the *Mining Journal* to be both ingenious and, on the face of it, applicable to refractory ores.

Alterations in the French Telephone Tariff.—The charges made for the use of the public telephones are to be modified. The price for five minutes' use of the telephone for Paris is to remain unchanged at 50 centimes. For the use of the long-distance wires the charge will be variable, according to the distance, and will be calculated at the rate of 50 centimes per 100 kilometres for every five minutes' conversation. Thus the charge of three francs now made for five minutes' conversation between Paris and Marseilles will be raised to at least four francs, as the distance separating the two places is over 800 kilometres. On the other hand, the price for the use of the telephone existing between Rouen and Paris will be reduced to 1 franc 50 centimes.

St. Pancras Vestry.—The Parliamentary and Lighting Committee of St. Pancras Vestry have had recently before them several notices of intention to apply for electric lighting Provisional Orders. After considering the matter, the Vestry have decided to send a reply to the effect that, the Vestry having an Order under the Electric Lighting Act, have referred the same to a committee with a view to make inquiries and to obtain estimates for the establishment of electric supply under the Vestry's own control, and that, until the Vestry have received and considered the committee's report, they are not prepared to entertain the consideration of the notices. Mr. T. B. Westacott, a member of the Vestry, has reported that the estimated cost of supplying the parish with electricity would be at first £50,000.

A New Storage Battery for Tramway Work.—The following is the description of a storage battery for tramway purposes, which has recently been brought out by the Société l'Electrique of Brussels. The battery consists of hollow cones of lead 30cm. in diameter, 20cm. high, and 3mm. thick. The external surface of each cone carries a number of projections, which serve the double purpose of supporting the active material and of keeping the cones apart. The internal surfaces are covered with litharge, and the external surfaces with minium, and thus each cone plays the double *rôle* of positive and negative plate. The cones are mounted one inside another, and the spaces between them filled with sulphuric acid, the projections forming the contacts. A high output for weight is claimed for this battery.

Exports of Electrical Apparatus.—The Board of Trade Returns for September show that our exports of electrical apparatus during the past quarter were below the average. The aggregate value of our exports to date is still higher than it was in 1887 and 1888, but the falling off during the last few months is rapidly wiping out the exceptionally favourable comparison of the first six months. The following is a comparative statement for the past three years :—

	1887.	1888.	1889.
January 1 to June 30 ...	£188,812	£244,213	£576,456
July	195,950	21,571	32,909
August	114,162	110,323	46,452
September	158,140	21,032	38,099
Nine months	£657,064	£397,139	£693,916

The Ries Traction Increaser.—The electric traction increaser devised by Elias E. Ries, of Baltimore, has just been tested with satisfactory results, says *Engineering News*, on the Philadelphia and Reading Railroad. The trials were made on the Frackville grade, 185ft. per mile. The apparatus, it will be remembered, consists of a small dynamo and engine mounted upon the locomotive and furnishing a current, which is passed from the forward to the rear driving wheels, through that portion of the track rails lying between them, causing an increased friction between the wheels and the rails. This arrangement is claimed to be far superior to sanding the tracks. With the dynamo running and a train of 45 cars attached to the locomotive, the ascent was made in 28 minutes, while without the current a trip over the same ground, with the same train behind, required 55 minutes.

Underground Electric Lighting Cables in the Strand.—During the past week or so Messrs. Siemens have been laying a cable on the south side of the Strand for the London Electric Supply Corporation. The cable is a concentric one, the insulation between the central and tubular strands being a fibrous material saturated with paraffin wax. Over the tubular strands follows a waterproof compound and an iron sheathing consisting of ribbon wound on spirally, and then hemp outside. The over-all diameter is about 2½in. The cable is laid in a trench about 9in. wide and 12in. deep cut in the footpath. Certainly, for cheapness and simplicity in laying, this system leaves nothing to be desired—at least, when the cable passes above the buried tangle of drains, water and gas service pipes, &c., as in this case. How such cables will fare when the British labourer with pickaxe and shovel appears on the scene it remains for experience to prove.

Reforms in the Cuban Telegraph Service.—Spanish advices from Cuba state that General Salamanca, the Governor of the island, has issued a decree, subject to the confirmation of the Home Government, introducing modifications into the service. It is proposed to cancel the existing tariff for interior telegrams and to substitute the following scale, viz.:—telegrams from 1 to 10 words, including address and signature, 20 centavos (1 centavo = ½d., about); 10 to 15 words, including address and signature, 40 centavos, and 5 centavos for each additional word, whatever be the length of the telegram. It is also proposed to receive urgent telegrams at three times the ordinary rate! The progress of telegraphy in Cuba evidently leaves much to be desired. Prepaid replies to the extent of 30 words will be allowed. The use of the French and English languages will be allowed, and the prohibition of the use of telegraph codes for the interior, under the decree of December 20, 1876, will be withdrawn.

Telegraphic Communication between Liverpool and Havre.—A discussion recently took place in the Havre Chamber of Commerce respecting the delay in establishing direct telegraphic communication between that place and Liverpool. M. Coupery, who brought the matter forward, explained that the dispatch of telegrams to either Hamburg or Bremen only took three-quarters of an hour. A message might go from Liverpool to Mulhouse, by using the Bremen route, in an hour; but between Liverpool and Havre it took from four to five hours. M. Rispal said that the establishment of direct telegraphic communication between Liverpool and Havre was one of the conditions of the arrangement come to between France and England for the working of the sub-marine Channel lines. After some further discussion, the Chamber decided to write to the Minister of Commerce, pointing out this unsatisfactory state of things, so prejudicial to the trade of the port of Havre, and soliciting his intervention to remedy the same.

Obituary.—Major-General Robert Murray, R.A., C.S.I., of the Bengal Staff Corps, late Director-General of Telegraphs in India, died on Saturday last at Ryde, Isle of Wight, at the age of 60. He entered the Hon. East India Company's service in the Bengal Artillery in June, 1845, serving in the Punjaub campaign of 1848-9, taking part in the action of Sadoolapore, in the battles of Chillianwallah and Goojerat, and in the advance to Peshawur. He received the medal with two clasps for these services. From 1857 he was employed in the Indian Telegraph Department, and from 1878 till 1883 was Director-General of Telegraphs in India. He became a colonel in 1876. In 1884 he was created a C.S.I., and in 1886 was advanced to the rank of major-general, when he was placed on the supernumerary list.—We regret to learn of the sudden death, on October 3rd, of Mr. Henry Sach, Telegraph Superintendent Great Eastern Railway, at the age of 60 years. The deceased had been superintendent of telegraphs for 43 years in the service of the Electric and International Telegraph Company, and since the transfer of the telegraphs to the Government he had been with the Great Eastern Railway.

THE BIRMINGHAM EXHIBITION.

THE SNELGROVE ELECTRIC WEIGHING MACHINE.—This weighing machine, the invention of Mr. William Snelgrove, is manufactured by Messrs. W. and T. Avery, of Birmingham, and may be described as a self-balancing, self-indicating weighing machine of the knife-edge steelyard type, which, as is well known, is the only form of weighing machine that can with safety be depended upon for accurate results. By the aid of electricity Mr. Snelgrove has succeeded in combining this accuracy with the self-indicating advantages of the spring balance. The machine exhibited at Bingley Hall indicates up to 10cwt. and shows variations of 1lb., and the general construction of it is shown in Figs. 1 and 2. The steelyard or beam B (Fig. 2) rests on the knife-edge centres, K, and the weighing platform is hung from the rod W. The balance weights consist of riders or poises, R and P, running on small wheels, and are driven along the guide rods by means of the motor shown in Fig. 1. They come to rest when there is perfect equilibrium, and their positions are indicated by figures painted on revolving dials, similar to those of an ordinary meter. There are two poises or riders in the machine—a small one, R, for indicating pounds, and a large one, P, for quarters and hundredweights. The position of the former is indicated by the dial-circle C_1, that of the latter by the large circle C_2. To prevent undue oscillations a brake, V, is introduced, which presses against the end of the arm A, which is rigidly attached to the beam; the brake is under the control of the electro-magnet D, and the pressure can be regulated by the small adjustable weight E.

Each poise has spur teeth cut on its under side which gear into a small wheel driven by the motor, and ratchet teeth on its upper side which engage with a pawl fixed to the beam. The use of this ratchet and pawl is to prevent the backward motion of the poise which would result from the compression of a spiral spring, which is wound up during the outward travel. The gear wheels, of which there is one for each poise, are loose on a spindle driven by the motor, and each wheel is set in motion by means of a clutch controlled by an electro-magnet. Fig. 3 shows one of these clutch magnets, with gear-wheel, rack, &c. As will be seen, the clutch H is thrown in and out of gear by the arm L worked by the magnets O or P. When a weight is placed on the platform one end of the beam rises, and with it the arm A (Fig. 2); this causes a contact with the terminal T_1 which is fixed to the support or carrier S attached to the base of the machine. An electrical circuit is now closed, which includes the brake magnet D, the motor relay and the small poise clutch magnet. The motor begins to drive the small poise along its guide, which continues to travel outwards until it strikes the switch lever F, which throws its own clutch magnet out of circuit, and puts into circuit that of the large poise, which in turn begins to travel outwards until the weight is lifted and the beam B drops. Contact with T_1 is now broken and made with T_2. The large poise clutch is now thrown out of gear, and remains stationary, being held in position by means of the pawl already mentioned; at the same time the small poise pawl is released, and the poise itself travels slowly back again under the action of the spiral spring, which now unwinds. This backward motion continues until equilibrium is established, when the arm A stands between T_1 and T_2,

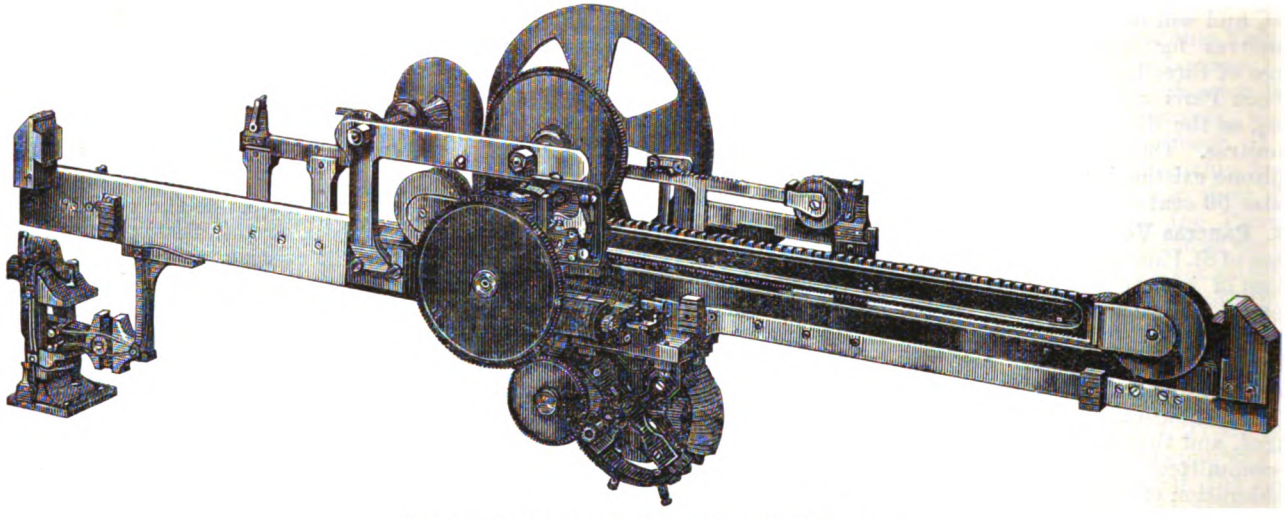

FIG 1.—Snelgrove's Electric Balance (Back View)

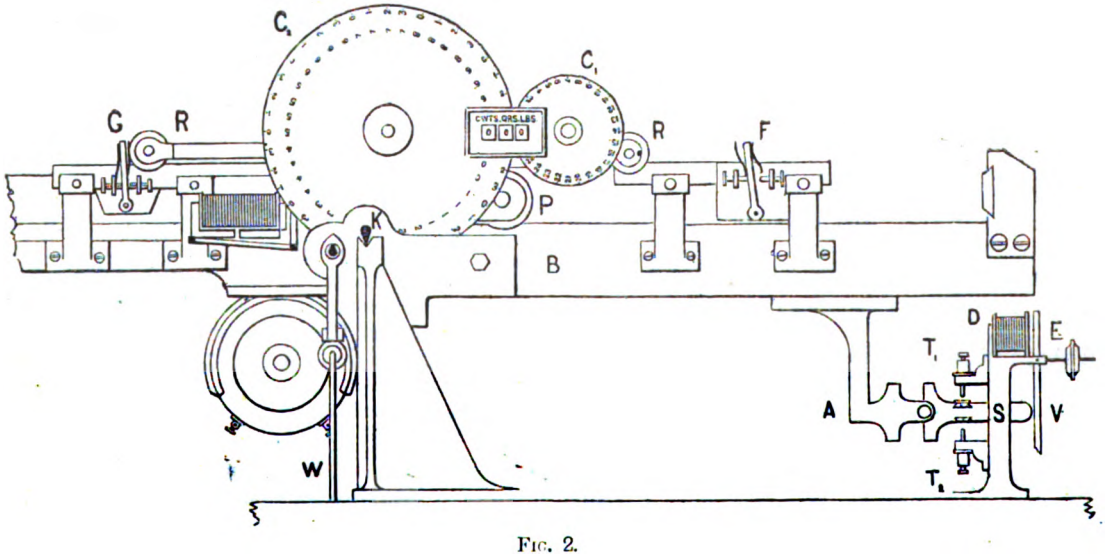

FIG. 2.

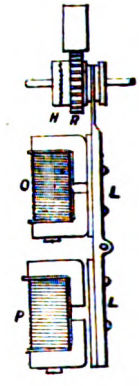

FIG. 3.

Digitized by Google

all circuits being broken and the weight being indicated by the dial circles. If the load on the platform is too heavy for the machine, the large poise runs to the end and strikes a switch, breaking the electrical circuits and bringing everything to rest. When the weight is removed from the platform, the beam drops on to the contact T_2, the small pawl is again released, and the poise R travels back, and on reaching the end—its original position—moves the switch G, which now releases the large poise pawl, allowing it also to travel back, when it finally touches another switch, and breaks the electrical circuit entirely. It will be seen, therefore, that the whole arrangement is entirely automatic, and cannot come to rest until equilibrium is established and the weight correctly given on the dials. The whole process of weighing is completed in a very short space of time, considerably less than that required for working the ordinary weighbridge and steelyard machines in everyday use. The power required by the motor is very small, a few Leclanché cells being sufficient to work it, and as the electrical connections and switches are automatically controlled by the mechanism no skilled attention is needed to operate the machine.

SAYERS AND STURGE'S SUSPENSION FOR ELECTRIC LAMPS.—An ingenious and simple arrangement devised by Messrs. Sayers and Sturge is exhibited for the suspension of arc and incandescent lamps. Its object is the avoidance of the dangling

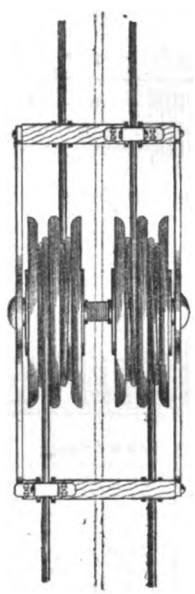

FIG. 4 (front view.)

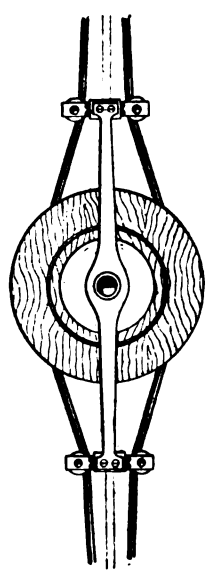

FIG. 5 (side view).

cords and swinging leads that usually accompany arc lamps and electroliers when they are required to be pulled up and down. For arc lamps the device takes the form of a block shown in Figs. 4 and 5, for glow-lamp electroliers it slides up and down a central guide bar. As will be observed from Fig. 4, there are two blocks round which the leads are wound, each block having two grooves turned in it with a flange between. The flexible lead is wound in one direction round one half of the pulley, then passed through a hole in the flange and wound round the other half in the reverse direction, and is thus carried down to the lamp without any joint or sliding contact. When an arc lamp is lowered, or an electrolier pulled down, the block descends through half the distance. The leads are re-wound when the lamps are pushed up, by the action of a flat spiral spring fitted inside the block.

DISTRIBUTION OF ELECTRICITY IN CHELSEA, &c., WITH ACCUMULATORS AS THE MAIN SOURCE OF SUPPLY.*

BY MAJOR-GENERAL WEBBER, C.B.

(Concluded from page 483.)

DESCRIPTION OF THE AUTOMATIC REGULATOR OF THE ELECTRIC POWER STORAGE COMPANY.

The charging mains arriving from the generating station are divided and connected to the groups of mercury cups of two "*charging circuit relays.*" These relays, C_1 C_2 (see Fig. 8), are identical in construction, and are really rocking switches, and come into action at the moment when the half batteries are just in or out of charge. Their function is to introduce into the charging circuit a carbon resistance, O, between the time that one half battery goes out and the other enters the position of being "under charge." The groups of four cups on the outsides of these relays are half positive and half negative, and the relative positions of the arms incline in the same direction. To pull them into those positions and maintain them there, each arm is actuated from below by two electro-magnets placed in a local circuit, to which I will refer further on. When the right-half battery S_1 is in charge, the right relay C_1 is in contact on its right (as it presents itself on the diagram). The positive and negative cups are respectively in connection with corresponding cups on the outside of the right-hand *transposing switch* A_1. The intermediate terminals are severally connected with the poles of four sets, each of 54 cells, so that these 216 cells are in circuit in series. On the way to the right-hand *charging circuit relay*, the positive conductor has formed the coils of a *charging solenoid*, marked E. Its function is as follows:—When the current is passing, the solenoid closes a valve in connection with a little gasholder, F, used to collect the hydrogen gas formed by one plate in one of the cells under charge. This cell is called a *master cell.* When no current traverses the coil of the solenoid, the valve is open, and no gas is retained in the holder. At this point the duty of the holder F may be described. When the half battery is approaching full charge, gas is given off, and the valve alluded to being kept closed by the charging current, gas is retained by the holder, and commences to fill it. The gas given off is collected first in an ebonite *gas chamber and acid trap*, marked H. The trap prevents any gas from this particular plate going anywhere else than into the gas chamber. From the *chamber* the gas passes into a bubbling-bottle, G, with oil in it, which is intended to extract the moisture, and thence to the little holder. The size of the holder is calculated so as to contain just sufficient gas as will be given off by one plate after the proper state of *milkiness* of the cell has been attained. The moment it fills, a contact is made with the arm of a switch which is underneath it. The switch closes the *local circuit*, to which I have already alluded as actuating the pulling-down magnets of the charging circuits C_1 C_2.

To return to A, the right-hand *transposing switch.* Let it be remembered that its right-hand contacts are dipped in their cups and the left-hand contacts are elevated out of them, and the charging current can go nowhere else but through the half battery. Meantime, discharging into the lamp system is going on from the left-hand half battery, and while this is going on the right-hand contacts of the rocking arm of the left *transposing switch* are dipped. These contacts are so arranged and connected with the poles of the four sets of cells that they are in position to discharge in parallel. It is evident that when the positions of the rocking arms of the two transposing switches A_1 and A_2 are reversed, the left half battery will be "in *charge*" and the right half battery discharging; and, again, that if the inner ends of the two rocking arms are dipped and they stand with opposing angles, then both half batteries are discharging, and charging has ceased.

Let us return to what takes place at the moment the arms of the switches rock into a fresh position. Underneath each of these arms, as in the case of those belonging to the charging circuit relays C_1 C_2, are placed two electro-magnets to pull them down. These electro-magnets are also placed in the local circuit mentioned twice before. This operation of rocking over, so to speak, is sufficiently slow between the break and make in the mercury-cups as to allow an interval of disconnection of less than half a minute. During this interval the charging current does not cease, but for the time, as has been already described, is relayed through the resistance O by the operation of the *charging circuit relay* C_1, the rocking arm of which, instead of moving slowly like that of the *transposing switch*, moves instantaneously. The operation is effected in the following order and manner:—As has been stated, the gasholder closes the local circuit in the pull-magnets under the elevated end of the rocking arm of the right-hand transposing switch, which com-

* Paper read before the British Association in Section G, Newcastle, September, 1889.

Digitized by Google

mences to move slowly over, aided by a balance weight rolling in a groove on its upper side. As the charging contacts leave the mercury other contacts under the arm break the current in the pull-down magnet of the outer and of the *rocking arm* of the *charging relay*, which, being weighted, falls the other way, and effects simultaneously the introduction of resistance, O. The rocking arm of A A_1 continues moving slowly over. It first makes the contacts, which bring the right half battery into the position of discharge in parallel, and finally makes other contacts, which, acting on the local circuit through a small rocking switch, starts the rocking arm of the *transposing switch* A_2. Its first action is to cut the left half battery out of the lamp system, and when it completes its journey to throw the left half battery in series into the charging circuit. At the same moment, by a separate contact, it closes the local circuit which actuates the pull-down magnet of the charging-circuit relay C_2, the effect of which is simultaneously to transfer the charging current from the resistance O to his next duty. When the left half battery is charged, the next and final stage is carried out by the gasholder acting as before on the local circuit, the work of which is confined to inciting the rocking arm of the left-hand *transposing switch* to rock over, so that the second half battery goes to the assistance of its fellow. A tell-tale wire back to the generating station from the transposing switch actuates a relay at the generating station the moment that the left-hand contacts lift out of the mercury. The current so transmitted actuates a relay which cuts off steam at the generating station.

of a carbon filament which is in circuit with the coil of M. This alteration of length, which minutely varies the resistance, is caused by the expansion and contraction of alcohol in a bent glass tube which presses on a column of mercury, into which one end of the filament is inserted. As the bulk of the alcohol alters through temperature the mercury is pressed up or down, and less or more of the filament is short-circuited. In order to maintain an equal discharge from each half battery, a *current balance*, marked K, is used. This apparatus is made of two coils of large section copper, wound spirally apparently, but really cut out of a piece of copper tube. The whole current from each half battery passes through one of these. Should one half battery be giving current at such a rate as to run some 10 per cent. below the other, the coil acts solenoidically and completes the circuit in D_1 or D_2, whichever may be affected, and thereby, through the intervention, as before, of one of the resistance switches B, cuts out one of the counter E.M.F. cells. The reduction of counter E.M.F. to the half battery which has been under discharging at once brings the two half batteries up to the same line. The diagram shows at two places the connection to which the feeding mains of each kind are led. At T is placed an ammeter to measure the total discharge into the feeding mains, which can be cut in or out. At the other pole is shown a set of safety fuses; these are also used on the other pole.

Of course there are many minor very important and interesting features of this beautiful invention of Mr. F. King's to which I have no space to allude. The small relay, marked N on the drawing,

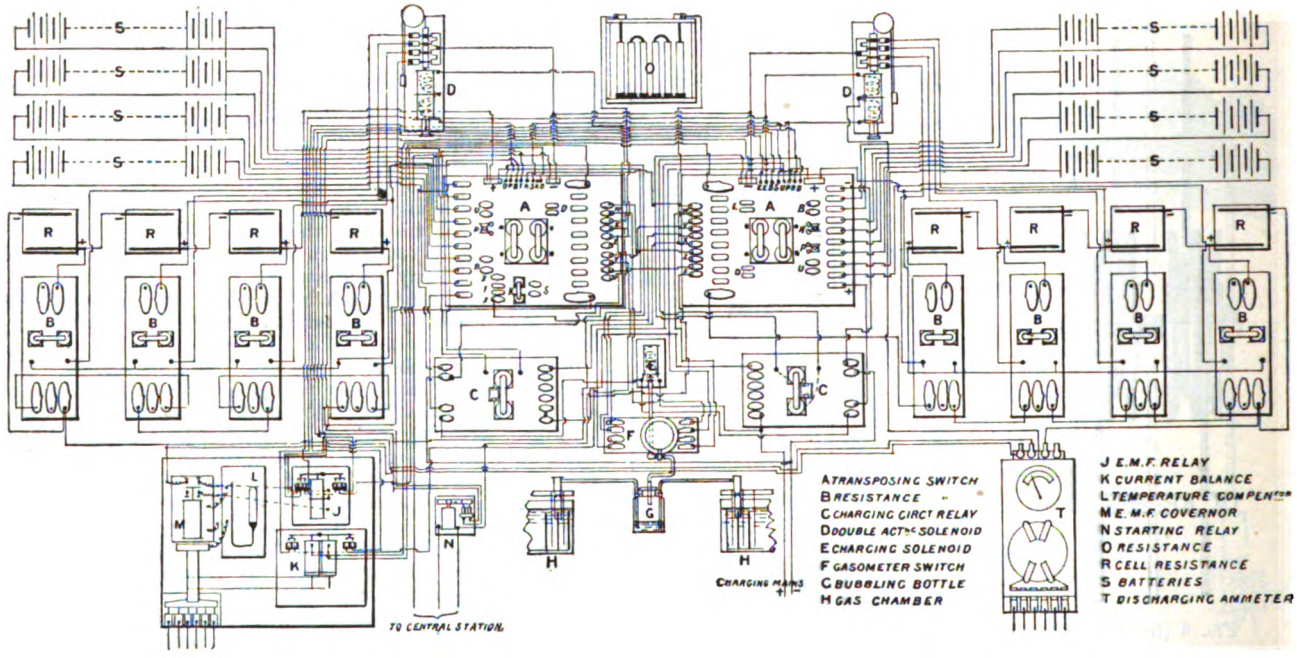

FIG. 8.—Automatic Regulator of the E.P.S. Company, as employed at the Chelsea Sub-Station.

On each side of the diagram are shown four resistance cells of the same type as those for accumulating, marked B, etc. The duty required from them is as follows:—1. To supply counter E.M.F. with which to regulate the pressure in the lamp system. 2. To give the required energy to actuate what has several times been referred to as the local circuit, of which there are actually two—one for each side of the apparatus.

This brings us to the consideration of what occurs in discharging from the batteries. In a system requiring a pressure of 100 volts, varying 1½ per cent. above and below, that from 54 cells is excessive, even allowing for the fall between the station and the ends of the feeders. At the same time it is necessary to have ample reserve to meet occasions of heavy discharge. To keep the pressure constant at the ends of the feeders, there must be tell-tale wires from those points to the E.M.F. governor M, fixed on the governing board. This apparatus is a fine wire coil in parallel with the feeders, and its function, when the E.M.F. is above or below the normal limit, to move a solenoid up and down. A lever bar connected with this completes a local circuit in a relay marked J, which in its turn actuates the two double-acting solenoids D_1 and D_2, which operates simultaneously on sliding contacts in connection with *resistance* switches B_1 B_1 B_1 B_1 and B_2 B_2 B_2 B_2. These solenoids act as rheostats on the discharging circuit, by putting in or taking out the counter E.M.F. cells one at a time, and even two at a time. The E.M.F. governor M is also in series with a temperature compensator, marked L. This little apparatus keeps constant the resistance of the fine wire coil of M by altering the length

has not been described, but I think it desirable to call your attention to it, not with the object of including it in the description, but in case any question may be asked about it. It completes the local circuit and causes switch A_1 to be brought into position of charge. It is actuated by a current from the generating station when the engineer is ready to start charging.

It is claimed for the system which has been under description:—That the cost of the *generating* and *storage* plant does not exceed that of any other system. In support of this, I have a calculation before me, made by the Electric Power Storage Company for a generating and storing plant for 30,000 30-watt lamps at £45,000, or at the rate of 30s. per lamp. On the same lines, the actual cost in Chelsea for a 9,000-lamp plant has been 40s. per lamp. Under the best conditions, the generating plant itself need not exceed an indicated capacity one-half of the maximum capacity of the system, assuming that the proportion of energy for which the consumers will pay is at least 70 per cent. of the energy produced at the terminals of the charging dynamos. The economy in space thus acquired is equivalent to the demand for space for storage. It is also claimed that the cost of the mains is less than in any other system. And, again, it isclaimed that the *working cost* must necessarily be considerably below that of any other system on account of the working of the motive plant always at its full power. To this particular feature of the system I wish to draw marked attention, together with the economical advantages in working, arising out of the complete stoppage of the machinery in motion each day for periods varying according to the time of year.

Specification of the General Conditions to be complied with in Wiring Houses for the Electric Light.

Compiled for the use of the Customers of the Chelsea Electricity Supply Company (Limited).

The contract under this specification includes all conductors commencing at the point where the Supply Company's work ends, and all electrical fittings which do not actually form part of the lamp fittings. It includes no lamp fittings unless otherwise specified.

1. Except where otherwise specified, the whole of the work to be carried out in accordance with the rules of the Society of Telegraph-Engineers and Electricians, and the Company in whose office the building is insured.

2. In every room or closet throughout the house one light will be separately controlled by a switch at the door, placed so as to be of easy access to the hand immediately the door is opened. In dressing and bed rooms this light will be suspended over the dressing-table, the length of the lead to permit of the lamp fitting being about 7ft. above the door. In other rooms the light to be so controlled will be selected as being the one most likely to be in common use.

3. No lamp lead is to be less in cross-section than the equivalent to a No. 18 S.W.G., and in the case of floor connections less than No. 16 S.W.G.

4. All mains and sub-mains where not carried between floor and ceiling, will be placed in approved wood casing. Where carried between floor and ceiling, they will be laid between the joists or in notches cut in the same, not less than 6in. apart, and in no case will any pair of leads be carried between the same joists or through the same holes in partitions, etc. They will be painted throughout with asbestos paint: positive red, negative black.

5. Wherever between floor and ceiling branches leave the main, they will be laid with sufficient slack, so that the branches shall not approach nearer to the main of the opposite pole than 6in., the necessary cleats being attached to, and holes bored in the joists to secure that end.

6. When the lamp leads serve lamps in rooms with wainscoting or ornamental walls, where casing is not suitable, they will be led separately and by different routes to the point where the lamps are fixed, following the lines of the molding or ornament; in such case they will be uncovered and fixed with saddles, and in no case, except where casing is used, may lamp leads approach nearer than 2in. of each other.

7. Where there are wall hangings or tapestry the lamp leads will be carried behind the same, if not in casing, as prescribed for, between floor and ceiling.

8. In the case of plain walls lamp leads will be laid in casings from the floor upwards, or the ceiling downwards, which will be let into channels cut in the walls. Should it be desirable not to disturb the decoration or paper, they will be laid on the face of the wall, and secured by saddles. In such case the colour of the covering of the conductor should harmonise as much as possible with the colour of the walls.

9. A wooden wall block will be fixed at every point where a lamp, wall plug, switch, or cut-out, are specified to be fixed under the contract, except where panelling or stone ornament already exists, when special means of attachment must be arranged for.

10. Distribution-boards will be supplied and fixed if required, and will carry the following fittings, besides the necessary terminals. To each circuit and sub-circuit will be furnished a switch and double-pole cut-out.

11. When a distribution-board is not required, a cut-out will be fixed at, or as near as possible to, the junction with each principal branch with the main.

12. Cut-outs will not be fixed at any other point in the system than those referred to in 10 and 11 except at each lamp.

13. Wall plugs, unless otherwise specified, will be fixed 2ft. 6in. from the floor, and where there is a dado they will be fixed above the top rail.

14. Floor plugs will make connection through a plate of insulating material laid flush with the floor, and the sockets will not be less than 3in. apart, and must be open at the base, so that dust may fall through into a cavity beneath.

15. Unless otherwise specified, the ends of the leads to serve lamps, of which the fittings are destined to be attached to the walls, will be left, so that the future fittings can be fixed anywhere between 4ft. 6in. and 7ft. above the floor.

16. Samples of all electrical fittings of every kind, and a drawing of the distributing boards will be submitted, and be subject to approval before being fixed.

17. Any deductions from, and additions to, the contract will be made only under instructions in writing from the superintending engineer, and no day work will be undertaken without his instructions; and no claim for such day work will be admitted unless a daily time-sheet for the same is handed to, or sent to him on the following day.

To this follow pages on which to draw up the number, nature, and position of the lamps, the descriptions of the route of each circuit, and a form of agreement to be entered into by the contractor.

Specification for the Supply and Laying Down Underground of Electrical Mains for the Chelsea Electricity Supply Company (Limited).

The contracting company is the Callender's Bitumen Telegraph and Waterproof Company (Limited).

1. *Route.*—The routes to be followed to be as nearly as possible those shown in the plans attached, but where necessary by reason of unforeseen obstructions they may be changed subject to the approval of the Chelsea Company.

2. *Excavation.*—The trenches to be made in the foot or roadways as the case may be to be on the routes described. The depth under the footpaths shall be as little as is consistent with safety. When under the roadways the depth of the trench shall be two feet under, or such other depth below the surface level of the roadway as the nature of the paving or macadam may require. When necessary, to avoid existing obstacles, pipes, &c., this depth may be increased or diminished, subject to the conditions of safety.

3. The existing paving of all kinds to be removed, and on completion of work replaced. The execution of the whole of this portion of the contract to be subject to the satisfaction of the surveyor of Chelsea parish, and to be carried out in terms of any orders or rules he may lawfully make, and to conform to conditions laid down in Clauses 13 to 19 inclusive, and in Clause 76 of the Chelsea Electric Lighting Order Confirmation Act of 1886, 50 Vic., cap. xviii.

4. *Open Trenches.*—The work to be so carried out that no one section of greater length than 100ft. shall remain open for 48 hours.

5. *Notices.*—All the notices which are laid down in the above-named Act as obligatory in connection with the works shall be given by the Chelsea Company, who shall relieve the contracting company of any responsibility in consequence of any neglect on the part of the Chelsea Company to comply with the requirement, but at the same time the contractors shall be required to give the Chelsea Company ample notice over and above the time of notices prescribed by the said Act to enable the Chelsea Company to fulfil its conditions; and, in case of the contracting company's defaulting to do so, the said company shall not be relieved from loss or responsibility arising out of any such failure on their part.

6. *Plans.*—The plans and drawings made in duplicate, as prescribed by the said Act, shall be prepared by the contracting company and delivered to the Chelsea Company.

7. *Deposit.*—Any deposit which the Vestry may require as a guarantee for the proper reinstating of the footpaths and roadways shall be made by the contracting company, and all arrangements connected with the same shall be made directly between the Vestry and the said company.

8. *Negotiations with Vestry.*—Although the Chelsea Company shall give all the legal notices required by the Act, or otherwise, the negotiations with the Vestry, their surveyor, or contractors, as to the actual mode and time of doing the work shall be carried on by the contracting company, advice of same being given to the Chelsea Company.

9. *Cable Cases.*—In the trenches as described, cable cases shall be placed and jointed together into continuous lengths. The cases shall be of the Callender-Webber type, of the sizes and with the number of ways as specified in the schedule.

10. *Cable Cases.*—The cases shall be made of the best bitumen concrete, of the same quality as those laid in 1887 at the Borough-road works of the Anglo-American Brush Electric Light Corporation (Limited). The thickness of material between the individual ways and between the ways and the outside of the case shall be at least half an inch. The inside of the ways shall be made truly circular in section and equal in area throughout, smooth and free from projections or roughness of any kind.

11. The cases shall be made in lengths of 6ft. each, the ends trued to fit each other, and they shall be jointed together by means of saddle-pieces and bitumen cement, and with the assistance of suitable mandrills for each separate "way," so that the ways shall be equal throughout and watertight, and the inside of the ways at the joints in every respect of the same section, within at least $\frac{1}{16}$th of an inch, as smooth and free from roughness as elsewhere. Tight joints shall also be made between the E.M.F. draw, and service, boxes, and the length of casing which join them.

12. No bends shall be allowed of a shorter radius than ——; they shall all be such as will allow the cables to be drawn in or out with ease, and the line of casing shall be laid out to avoid all unnecessary divergences from the straight or level. No curved

Digitized by Google

length of casing will be used in which the circular section of the ways has been altered in form by the process of bending.

13. Drawing-in cords to be provided by the contracting company, and left in the ways as and when the cases are laid. When cables are drawn in, these cords to be used for drawing in the necessary drawing wires, which will be recoverable by or be returned to the contracting company, remaining their property in the interim.

Drawboxes.—14. Drawboxes to be provided at all points as follows:—

a. All changes in direction of line of 90deg. or thereabouts, or where changes of direction prevent the use of curves.

b. At all points of junction between one main and another.

c. Sudden alterations in level.

d. All straight lengths, in which boxes do not occur for the above reasons once in every hundred yards.

15. The drawboxes must be securely joined to the main casing. The covers of the boxes to be of cast iron, resembling the Post Office specification of weight and thickness, and to be of the designs, dimensions, and patterns agreed on between the managements of the two companies.

16. If during the progress of the work it is found expedient to place additional boxes, this shall be done by the contracting company on orders being given by the Chelsea Company.

17. *E.M.F. Boxes.*—The distributing or E.M.F. boxes to be placed at the points shown on the attached drawing and marked——, or elsewhere, if required. They will be constructed of brickwork in cement, or laid in bitumen, and with floors and covers of best York landing. They will be constructed on the general design shown on the attached drawing, modified to suit the particular conditions of each case. The copper junction pieces to which the mains are jointed will be of special design, suitable to each position, and the joints with the same, and their insulation shall be made in all respects as mechanically and electrically secure as the joints in the rest of the system, described elsewhere.

18. *Service-Boxes.*—Service-boxes to be of cast iron, and to be provided and fixed in number at least one for every two houses as shown in schedule. These to be of the design, dimensions, and pattern, agreed on between the two companies. Wherever possible only one line of distributing cables to be interrupted and pass through these service-boxes. Service-boxes and house connections to be fixed either at the same time as the casing is laid or subsequently, as found most convenient.

19. The cables used to be made as follows:

Conductor.—The strand to be of copper wire of high conductivity guaranteed not less than 98 per cent. that of pure copper. Each wire to be tinned separately and to be of the size shown in schedule.

20. *Dielectric.*—To consist of a solid sheath of bitite (vulcanised bitumen) put on under pressure to a diameter of not less than the dimensions named in schedule.

21. *Tapes.*—The cable to be taped over the dielectric three times with prepared tape and compounded between each. Braid to be of hemp yarn closely plaited and served with liquid bitumen compound, then with an asphalte compound, and finally passed through blacklead to facilitate drawing into the way. The cables to be coiled on large drums, having a boss of not less than 3ft. in diameter, and not to be subjected during manufacture or afterwards to any undue strain by bending or otherwise.

22. *Joints in Cables.*—The joints between the sections of the cables, each to each, to be made by a long soldered joint in the conductor. The seven central wires to be run together solid, and each of the outer wires to be individually jointed to the corresponding wire in the other cable, the wires to be short and long alternately on each cable to form a strong marriage joint. The whole to be then bound with fine copper wire and soldered over all.

23. This conductor to be lapped with tape, and then covered in not less than three thicknesses with sheet bitite, made specially for this purpose. The whole to be well welded together, and to be finally protected by strong prepared tape and compound.

24. Each joint when finished to be tested for insulation and conductivity. In each draw and distribution box a maximum of 2ft. and a minimum of 1ft. slack to be left on each cable for the purpose of allowing the sections of cable to be drawn backwards or forwards a few inches from time to time to prevent adhesion to the insides of the cases, and to secure their freedom, and the possibility of at any time withdrawing the cables for the purpose of maintenance.

25. *Service Joints.*—The joints of service leads to the mains for house supplies to be T joints, and made as described above, except that the service wire will be jointed on the main by passing through the centre of the main, and lapping three times round the strand, the whole to be then firmly soldered and insulated as before described.

26. In the service-boxes care to be taken that the joint is as near as possible in the middle of the space, so as to allow the cable being safely moved when drawn periodically backwards and forwards to prevent adhesion. The service-leads to have sufficient slack in the box to allow of this being moved without strain to the mains.

27. *House Connections.*—House connections to be provided from each service-box to within the boundary-wall of the premises, and such connections to consist either of a two-way Callender-Webber case, or of a cast-iron pipe carrying two cables, each of the size required to supply the current to be agreed on with the customers. A price to be paid for all such connections as shown in schedule. This to include breaking through and making good the house or area walls.

28. During the execution of the work the Chelsea Company to have free access for purpose of supervision to all parts of the work, and their representative to have the right to reject any labour and material which he considers in the interest of the work should not be employed, and upon receiving written notice to that effect from him the representatives of the contracting company will cease to use the same.

29. Every separate length of cable shall be tested for its insulation resistance after having been drawn into the casing and placed *in situ* before being jointed to the next length. The result of each such test must give infinity with a Wheatstone bridge, Post Office pattern both between the conductors and between each conductor and earth; the current used to have an E.M.F. not exceeding 100 volts.

30. The next test will be of the same lengths when jointed together from end to end from a station to a feeding-box. From this test the same result will be required.

31. Similar resistance results will be required from the distributing mains before the house-service branches are joined in as from the charging and feeding mains.

[The discussion on this Paper will be given in full in our next issue.]

OBITUARY.

DR. JAMES PRESCOTT JOULE.

It is with profound regret that we have to chronicle another loss to science in the death of the great physicist, Dr. Joule, which occurred on Friday last, the 10th inst., at his residence at Sale, near Manchester. He was born on Christmas Eve in the year 1818, so that he died in his 71st year. The name of Joule is familiar to every student of physics through its association with the mechanical equivalent of heat, which was first determined by him, and is, therefore, commonly known as "Joule's equivalent."

Owing to his delicacy as a child Joule was never sent to school, but was educated at home by private tutors until the age of 15, when he began working in his father's brewery at Salford. His first instruction in the elements of mathematics, in natural philosophy, and in chemistry was obtained from the great chemist, Dalton, famous as the originator of the Atomic Theory, which laid the foundation of modern chemistry.

There can be no doubt that Dalton's teaching exerted an important influence upon Joule's future line of work, and was an important factor in leading him to devote so much of his energies to throwing light upon the obscure domains of molecular physics. Very shortly after his introduction to Dalton he began to experiment with physical apparatus of his own construction, and in the year 1837, when he was only eighteen years old, he constructed an electro-magnetic engine, which he described in "Sturgeon's Annals of Electricity" of the following January. Two years later he discovered the fact that there is a limiting value to the magnetisation which can be communicated to soft iron by means of the electric current, and investigated the numerical value of this limit by determining the sustaining power of an electro-magnet excited by currents of different strengths. The results of these investigations were published in a series of Papers "On Electro-Magnetic Forces," which appeared in "Sturgeon's Annals." In the course of one of these Papers, he points out the great difficulty, if not impossibility, of understanding experiments and comparing them with one another, "arising from incomplete descriptions of apparatus and from the arbitrary and vague numbers which are used to characterise electric currents." "Such a practice," he says, "might be tolerated in the infancy of the science, but in its present state

Digitized by Google

of advancement greater precision and propriety are imperatively demanded." This was written in the year 1840, and in his subsequent investigations he always employed a definite chemical unit of current of a value slightly less than two amperes. As unit of resistance he adopted that of a copper wire of definite dimensions, the variability in the resistance of different specimens of copper not being known at that time. These units were first described in a Paper "On the Heat Evolved by Metallic Conductors of Electricity, and in the Cells of a Battery during Electrolysis," published in the *Phil. Mag.*, in 1841. It was in this Paper that he showed that the heat developed by a current of electricity traversing either a metallic conductor or an electrolyte is proportional to the resistance of the conductor and to the square of the current strength. During the next three or four years Joule published a series of Papers describing investigations of the highest interest and originality, carried out with the experimental skill and minute accuracy in which he has always been simply unapproachable. The investigations opened up the hitherto untrodden fields of electrical and chemical thermo-dynamics. Want of space prevents our doing much more than calling attention to these Papers, but one important result obtained in them must be recorded, viz., that the total amount of heat evolved in a circuit composed partly of a metallic conductor and partly of a voltaic cell is equal to the total heat produced by the chemical action.

In a Paper "On the Calorific Effects of Magneto-Electricity, and on the Mechanical Value of Heat," communicated to the British Association at their meeting at Cork, in 1843, Joule proved that in magneto-electric machines mechanical work is converted into heat, and that the heat generated bore a constant ratio to the mechanical work absorbed. After this came the famous series of Papers in which Joule described in detail the experiments by which his mechanical equivalent of heat was obtained. These Papers are models of patient care, and of an accuracy which almost passes comprehension. The results described in them are too well known to require discussion here.

Among other important investigations of Joule's should be mentioned his research on "The Effects of Magnetism upon the Dimensions of Iron and Steel Bars," and his improvement of the tangent galvanometer by the introduction of a very small needle in place of the large ones previously employed.

Joule was an honorary D.C.L. of Oxford and honorary LL.D. of Edinburgh and Dublin, and a member, either honorary or ordinary, of a large number of scientific societies. In the year 1849 the Royal Society awarded him their Royal Medal for his celebrated Paper "On the Mechanical Equivalent of Heat," and it is worthy of note that this Paper, which was communicated by Faraday, was the first of Joule's Papers communicated to the Royal Society which was not rejected by them. Subsequently the Copley medal was also awarded to him.

Joule's work is remarkable, not only for its great accuracy in the most minute details, but for the deep insight into the processes of Nature which it exhibits, and for mathematical accuracy of expression combined with the almost complete absence of mathematical symbols.

The Physical Society has raised an enduring monument to this great leader of science by the publication of a very fine edition of his scientific Papers, compiled and edited by himself. The edition is in two volumes, the first comprising the Papers published by himself alone, and the second containing Papers which he published in conjunction with Sir William Thomson, Sir Lyon Playfair, and Dr. Scoresby.

SIR DANIEL GOOCH.

It is with deep regret that we record the death, after some weeks' illness, of Sir Daniel Gooch, Bart., which took place on Tuesday afternoon last at his residence, Clewer Park, Windsor.

Born at Bedlington, Northumberland, in 1815, he studied the profession of engineer at Newcastle under Robert Stephenson, and subsequently in the Tredegar Ironworks. In 1837 he became chief locomotive engineer to the Great Western Railway, after having been engaged under Robert Stephenson in his railway works at Warrington. He occupied this position for 27 years, at the close of which period he was elected chairman of the Board of Directors of the same company. The deceased baronet's public career is, however, mainly interesting on account of his having formed one of the small band of capitalists and engineers to whom we owe the establishment of telegraphic communication between this country and America.

In the year that Mr. Gooch became chief locomotive engineer to the Great Western Railway, the Atlantic Telegraph Company, disappointed by many failures, had become disheartened as to the chances of accomplishing their project of laying a cable to America, and confidence in the scheme was at the lowest ebb. The history of the company may be briefly told. It was projected in the year 1846, and six years were spent in its formation, as great difficulty was experienced in inducing men to support an enterprise considered by many utterly Utopian. The succeeding six years were consumed in abortive attempts to carry out the project, when at length the promoters were cheered by what seemed for a time the realisation of their labours. A cable was laid, and a message was sent from America to Europe, but communication soon ceased altogether. The cable was a failure. Another six years elapsed before the company were in a position to renew their efforts. Mr. Gooch was at that time a director of the Telegraph Construction and Maintenance Company, and in this capacity had given his attention to the subject of deep-sea cables; and he became convinced of the feasibility of the Atlantic cable project, and, having an interest in the "Great Eastern" steamship as one of the mortgagees, it occurred to him that the vessel could be utilised in carrying the cable out. The "Great Eastern" was sold for £25,000 over and above all liens upon her, Mr. Gooch being one of the purchasers. The "Great Eastern" Steamship Company was formed, with Mr. Gooch as chairman, and that company, the Telegraph Construction and Maintenance Company, Mr. (now Sir John) Pender, chairman, and the Atlantic Telegraph Company worked in unison. The "Great Eastern" sailed from England on July 15, 1865, carrying a cable of 5,000 tons. She sailed from the Thames, commanded by Captain (now Sir James) Anderson, Mr. (now Sir Samuel) Canning being in charge of the cable, and Mr. Willoughby Smith, chief electrician, with Sir (then Professor) William Thomson and Mr. C. F. Varley as consulting electricians, Mr. Gooch, Mr. Hamilton, and Mr. Cyrus Field being also on board. After connecting the cable with the land at Valentia, the "Great Eastern" steamed into the Atlantic on the 23rd July. Telegraphic communication with the vessel (interrupted by two faults due to defective insulation caused by pieces of metal pressed into the gutta percha coating, which were immediately repaired), finally ceased on August 2nd. The apparatus for raising the wire proving insufficient, the vessel returned. Subsequently the Atlantic Telegraph Company was reconstituted as the Anglo-American Telegraph Company (Limited). In June, 1866, the vessel sailed from the Medway with a new cable. The shore end at Valentia was spliced with the main cable, and the "Great Eastern" moved away on July 13th. By the 22nd of the same month 1,200 miles of wire had been laid. Five days later perfect communication had been established between Heart's Content, Newfoundland, and Valentia. The interest which Sir Daniel Gooch evinced in promoting the success of this great enterprise as Chairman of the Great Eastern Steamship Company and Director of the Telegraph Construction and Maintenance Company was promptly rewarded by a baronetcy. In addition to being chairman of the Great Western Railway Company and of the Telegraph Construction and Maintenance Company, Sir Daniel Gooch was a director of the Anglo-American, the Eastern and South African, and the Globe Telegraph and Trust Companies, and a Trustee of the Submarine Cables Trust. He was a deputy-lieutenant and Justice of Peace for Berkshire and represented Cricklade in the Conservative interest from 1865 to 1885. He was twice married, his second wife, who survives him, being a daughter of the late J. Burder, Norwood, Surrey.

Telephonic Extension in Hampshire.—The trunk line connecting Southampton and Winchester was opened last week. Three minutes' conversation is allowed for 6d. The trunk line between Portsmouth, Gosport, Bournemouth, Poole, Southampton, and Winchester will be completed before Christmas.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
	s. d.	s. d.	s. d.
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, **1,** *Salisbury-court, Fleet-street, London, E.C.*

THE PROFESSION OF ELECTRICAL ENGINEERING.

There was a time, and that not very many years ago, when the Church, the Bar, the Army or Navy, and perhaps the Medical Profession, were alone regarded as walks in life fit to be trodden by the sons of gentlemen. Engineering had not yet attained the rank of a Profession, but now it has become one of the most fashionable pursuits, and its many branches are crowded to an extent which makes anxious parents debate in their own minds whether, after all, they are doing right in allowing their sons to graduate for any one of them. The rapid development which has during the last few years taken place in electrical engineering, or to speak more correctly, the advent of this new branch of mechanical engineering, has naturally again raised their hopes, and the consequence is that in all institutions where technical education is given, the classes dealing with applied electricity are becoming more and more crowded. Ten years ago the English as well as the Continental technical schools did not include electrical engineering amongst the subjects taught. At the most there was given a course of mathematical or experimental physics, but of physics applied to useful arts—the theory of simple mechanisms, that dealing with the strength of materials and the theory of thermo-dynamics were the only subjects taught. Now a host of subjects, such as magnetism, electro-dynamics, electro-chemistry, the theory, and to a certain extent also, the practical construction of electrical machinery and apparatus have been added, the various schools and colleges recognising that to attract students it is necessary to give them tuition in that branch of engineering which at present is most fashionable because most promising. The popular tendency is decidedly in the direction of electrical engineering. Many an anxious father, who would not dream of making of his son a civil or mechanical engineer of the old school, will unhesitatingly

Digitized by Google

send him to a college which professes to turn out full-fledged electrical engineers in the term of a year or so, especially if the lad appears to have some aptitude for "electricity." This aptitude is generally gauged by his fondness for electrical playthings such as frictional machines, Leyden jars, Geissler tubes, induction coils, and so forth. Given a youth who likes to dabble with these tricks, and a father who is absolutely ignorant of engineering science, there is little wonder if the latter considers the former a veritable EDISON in a potential state, and agrees cheerfully to his taking up "electricity" as the proper and most promising line of study.

To such a father not less than to such a son we would strongly recommend the presidential address delivered by Prof. JOHN PERRY before the Junior Engineering Society on the 11th inst. Prof. PERRY was a mechanical engineer long before he became an electrician, and he spoke to an audience the members of which were not in doubt as to what profession each should choose, but had for the most part already made their selection of the particular branch of engineering each intended to follow. Yet his remarks deserve attention from those who have yet to make the choice, and if his advice is acted upon it will save a good deal of disappointment and generally raise the status and prospects of electrical engineers. This advice is briefly the following:—Let none aspire to become electrical engineers who have not first been trained for mechanical engineers. Not only is such training necessary to enable the electrician to design his machinery with due regard to the strength of materials and other matters generally dealt with by the mechanical engineer, and as important in a dynamo or arc lamp as in a bridge or a steam-engine, but without a correct conception of mechanical forces it is utterly impossible for anyone to appreciate the character of electric and magnetic phenomena. It is only when we are able to definitely estimate and express in some measure the forces of Nature that we can speak of them in a scientific sense—until we can measure these forces, we know nothing about them. It is true we may perform tricks in which these forces come into play; we can charge Leyden jars and give some persons a shock, or we can experiment upon them with a "medical" induction coil, but such experiments will not teach us how to build condensers and dynamos.

In the address we have referred to, Prof. PERRY dates the beginning of the period at which the mechanical engineer applied himself to electrical machinery from about 1878, and gives as the immediate cause the discovery of electric transmission of power. The date is wrong, though we quite agree with Prof. PERRY that prior to 1878 mechanical engineers had not paid any attention to the construction of dynamos. We would even go further, and say that it was only after the Paris Electrical Exhibition in 1881 that the mechanical engineers, and especially English mechanical engineers, began to ask themselves whether it would not be possible to make of that toy machine, then known as the wonderful "A" Gramme (in which the armature was a conglomeration of wood, iron wire, cotton-covered copper wire and tape, the whole held together more or less by glue and friction), a sound mechanical job. In our opinion, the advent of electrical engineering in the present sense dates from that period, but the discovery of electric power transmission dates back to 1873, and took place at the Vienna International Exhibition, whether by sheer accident or not is a disputed point. If we consider that so valuable an application of dynamo machines was already known sixteen years ago, and has only been developed during the last few years, we must come to the conclusion that mechanical engineers have missed their opportunity for a very long time. The transmission of power is a subject which appeals far more directly to the mechanical engineer than the production of the electric light, yet it has been left to the electricians who wanted to use the dynamo for lighting purposes to improve it so that it may serve their purpose. Had the mechanical engineers been able to appreciate the dynamo when it first came before the world this improvement would have taken place some eight or ten years sooner, and we should all be the better for it. If Prof. PERRY'S advice be followed by those he addressed on Friday last there is no danger that a promising field will be similarly neglected in future. He counselled every mechanical engineer to make himself acquainted with at least the rudiments of electrical engineering, pointing out that the application of dynamos and other forms of electrical machinery must be for ever increasing, and thus create a greater and yet greater demand upon the skill of the mechanical engineer. On the other hand, Prof. PERRY advises electricians to learn drawing, in order that they may be able to put their ideas on paper in such a way that a mechanical engineer may carry them out without having to re-design every part. It would thus appear that Prof. PERRY makes a distinction between electricians and electrical engineers. If we understand him rightly, he would have every electrical engineer capable of designing mechanical work, every electrician capable of making at least an intelligible drawing, and every mechanical engineer cognisant of Ohm's law and other elementary matters connected with electrical science. When once the profession is thus subdivided we might indeed expect great things, even, perhaps, the realisation of Prof. PERRY'S plan of obtaining motive-power by a combination of heat battery and electromotor, to which he referred at the close of his address. He had pointed out in 1881 that if a voltaic cell could be made in which coal is burnt instead of zinc, and the current utilised in driving an electromotor, 90 per cent. of the heat energy contained in the coal could be obtained in the shape of work instead of only 10 per cent. as now with a boiler and steam-engine. The difficulties were, however, the great size and cost of the apparatus required. Now, Prof. PERRY told his hearers that the difficulty of excessive size of apparatus had already been overcome. He and his partner (whose name, however, did not transpire) now see their way to develop one horse-power per cubic foot of apparatus. We hope that Prof. PERRY will ere long take the engineering profession into his confidence and tell them how this marvellous result is achieved. The question of expense, which still seems to stand in the way, might then possibly also be solved by the united efforts of the three sections of engineers which, according to his plan, should form the profession.

ON MECHANICAL ENGINEERING IN ELECTRICAL INDUSTRIES.*

BY PROF. JOHN PERRY, D.SC., F.R.S.

This Society expects from its President for the year an inaugural address, with whose subject matter he is supposed to have a special kind of acquaintance, and which is of importance to the Society.

As a mechanical engineer whose apprenticeship began twenty-five years ago, and who has paid a considerable amount of attention to electrical matters, I feel that I have a sort of experience which warrants my speaking to you on the subject which I have chosen for this address.

Unfortunately, however, I find, like others in such a position as this, that a man who is busily engaged not only in teaching, but also in active practice in the engineering profession, finds very little time for putting forward his notions with either the literary finish or the completeness of treatment which his subject deserves.

Until a few years ago the construction of electrical instruments and machines and their erection and use were altogether in the hands of electricians who knew little about electricity, and who knew almost nothing of mechanical engineering. At present the best

* Presidential address to the Junior Engineering Society, Oct. 11, 1889.

Digitized by Google

dynamos are made by experienced mechanical engineers who have somehow picked up a working knowledge of electricity, and for the last ten years I have tried to impress upon young electricians the necessity which exists for their learning how to make working drawings, and to make mechanical calculations, as well as for their being trained in the shops to use the hammer and chisel, and to learn the use of machine tools; in fact, that they must become good mechanical engineers as well as electricians. The electrical industries are more and more demanding the experience of the mechanical engineer. It is true that among the rank and file, for every hundred stokers, engine-drivers, fitters, and machine-shop hands employed there will always be need for perhaps ten men who may be called electrical plumbers; but I am not now thinking of the rank and file.

In 1860 it was almost unknown, and in 1870 it was very little known, that exact calculations might be made concerning electric phenomena: that is, that there was a science of electricity as distinguished from a mere natural history.

There were, indeed, publications in which the speculations of Franklin and other writers of from seventy to one hundred years ago on the nature of electricity, were fully entered into. Careful descriptions were given of rubbed glass-plate machines, of batteries of Leyden jars, the giving of shocks, the production of scenic effects by electric sparks, and the use of glass-legged stools. In general, such information was given as might be found useful by practical jokers. The information on Magnetism was of much the same childish order. The department of Voltaic Electricity, or Galvanism, as it was called, consisted of descriptions of various forms of voltaic cells, and of methods of joining cells together, so as to produce a maximum current in a circuit, with perhaps a description of the single-needle telegraph. The book was usually redeemed from worthlessness by some account being given of Faraday's experiments; but readers found that the main outcome of Faraday's work was the Ruhmkorff induction coil, whose most important function was to illuminate Geissler's tubes for children's parties. In fact, it may be said that up to 1870 the writers of books, and nearly all the teachers of electricity at schools and colleges, remained in a state of ignorance of everything except what may be called a list of electric tricks.

And yet the science of Electricity as we know it now had really been developed. The researches of Cavendish and Faraday and Joule were known to a few, and Sir William Thomson's magnificent series of Papers had been buried in journals and learned Society Transactions for, some of them, more than twenty years.

Now what distinguishes the engineer is this: he can design a thing which he knows will work if it is constructed exactly to his design. He makes exact calculations; but to do this he must have a quantitative knowledge of the phenomena he deals with. And the origin of Thomson's work, the origin of an exact knowledge of electrical phenomena, was this: Thomson was an engineer, he was engaged in practical telegraphic work of such a kind as necessitated his knowing quantitatively about the phenomena he was dealing with, and, like an engineer, he proceeded to acquire the necessary information; whereas the ordinary telegraph operator, the *quasi*-scientific experimenter and teacher, the popular lecturer, knew nothing of the fact that electricity can be measured. We cannot imagine a mechanical engineer regarding a few inches as being equal to a distance of some miles, or even of some thousands of miles, or his assuming that steel and brick are equally strong. We cannot imagine a grocer to confound an ounce of sugar with a ship's load of the same material; and yet these absurd notions give but too truthful an idea of the vagueness, of the general want of definiteness, which, till a few years ago, existed in the minds of nearly all men who called themselves practical electricians.

Observe that I am not contemning the labours of experimenters who did not have quantitative knowledge. In fact, the result of the work of such experimenters has very often been that an interesting problem has been put before the mathematical physicist, and it is sometimes forgotten that it is almost never the solver of a difficult problem, but really the setter of the problem, who is an inventor. I can throw ridicule upon the contrivances that I and many others have made in the past, but I know that the failure and partial success of such contrivances has taught us and the world how important it is to have an exact knowledge of the phenomena we deal with.

Such an exact knowledge of electricity is now readily obtainable, and it is well to consider how it was that this new engineering science was created with so much rapidity that in the last ten years a greater advance in its practical applications has been made than ever before in the history of the world.

Between 1860 and 1880, greatly in consequence of the work done by the Science and Art Department in this country, and its reflex action in other countries, some knowledge of the principles of electricity, which until then had only been known to a few people, became the property of thousands of mechanics, and it may almost be said that the rate of progress of electrical discovery became proportional to the number of people who had a little electrical knowledge. For example, what was wanted for the proper working of an arc electric light became known to many people, and in a short time hundreds of interesting methods of regulation were in use. The small magneto-electric machine, a toy for giving shocks and adding to the incomes of certain medical men, led to the machine of Wilde in 1866, which had electro-magnets. In that year Varley, who was Thomson's partner, and others, made independently one of the grandest discoveries of the century, and presently a machine was in use which excited its own field-magnets, the type of all dynamos ever since. With this principle of Varley's, and using the form of armature employed by Pacinotti in 1860, Gramme invented, some time later than 1871, his famous dynamo which first revealed to the world how large might be the output of electrical power from a small machine. All the time from 1866 to 1883 there was an ever-increasing number of mechanics contriving and trying their inventions, and demanding a clearer knowledge of electricity, and at length some of the few who had the knowledge put their knowledge in simple language before the world. The result was that in 1883 we had not only the Gramme and Alteneck or Siemens and Brush machines, but hundreds of others, which differed from one another mainly in mechanical construction. Even at this time there was no quantitative knowledge available concerning the magnetic circuit of the dynamo; but about five years ago Dr. Hopkinson, a well-known Whitworth scholar, discovered its law in seeking to improve that form of the Alteneck dynamo called the Edison, and showed that it was possible to have twice the output from a machine of given weight with a superior efficiency, so that now the simple laws not merely of the electric but of the magnetic circuit of a dynamo can be readily understood by any engineer, and in consequence the construction of dynamos and motors and other electrical contrivances is rapidly becoming as perfect as the construction of the modern steam-engine.

Let us give all honour to the experimenters who try all sorts of apparatus, some of them to be afterwards condemned as absurd, till they produce the germ of a useful invention; to the scientific men who use their mathematics and measuring instruments and give us exact laws. But we are not detracting from the honour due to these men when we also give credit to the mechanical engineers, without whom an invention would remain merely an interesting yet badly-constructed toy.

What particularly attracted the attention of the mechanical engineer to the new science from 1878 to 1883 was the fact that by means of a dynamo, A, driven by a steam-engine or water-wheel, and another dynamo, B, called a motor, and connecting wires between them, mechanical power in large quantities might be developed by B with very little loss in transit; that there might be many motors, B, worked from one or many dynamos, A; that the motors might work printing presses, or machine tools, or pumps and fans in mines and tunnels and other places to which communication of any other kind than by simple wires was almost impossible, or any other fixed machinery, or, again, railway carriages or tram-cars, or telpher trains in motion; and that electricity, the agent here employed, is not only capable of transmitting thousands of horse-power to immense distances with great economy, but it is an agent by means of which it is natural and easy to transmit signals and perform functions of a most complicated character at great distances, and so lends itself to most curious kinds of automatic working. They learnt also from Lane-Fox and Swan that the energy sent out by the same dynamo, A, could not only be used with accumulators, but be utilised in giving a most beautiful light, distributed in any required way, and they knew that the greater part of the work to be done in this new industry was purely and simply mechanical engineering.

The mere fact that dynamos could convert several horse-power was in itself enough to produce a revolution in one's regard for electrical matters. Hitherto we had looked upon telegraphy as a beautiful adjunct to railway and other kinds of engineering; but the power required to operate the telegraphic apparatus at Valencia is one one-millionth of a horse-power, and really, the transmission of this power from America, accompanied as it was by a waste on the road of something like 99 per cent. of the total power sent in at America, could hardly be regarded as having any connection with mechanical engineering. Hitherto the mechanical engineer had concerned himself with the machinery required to draw iron and copper wires, to cover wires with silk or cotton, gutta-percha or india-rubber; with cable ships and their steam-engines and propelling apparatus, and with the specially contrived machines for paying out cable and picking it up. In a thousand ways the electrical industries required the help of mechanical engineering, but in the very same sort of ways so did the ladies' dressmaking industries. The new discovery really amounted to the discovery of a new department of mechanical engineering, for it soon became evident that the dynamo A was analogous with a force-pump for water, and the motor B with a water-pressure engine, and the wires represented the communicating pipes in a system of hydraulic transmission of power, and that just as in the hydraulic system we could reduce the

Digitized by Google

loss in transmission either by increasing the diameter of the pipes or by increasing the pressure, so in the electric system we could reduce the loss either by increasing the size of the conducting wires or by increasing the electric pressure.

Of course, it was at once seen that as dynamos must be driven, steam-engines and boilers must be put up, and the belt, or rope, or friction gearing, or direct coupling employed in driving, could differ very little from what are employed in driving fans, pumps, and other machinery. In arranging a central station there would be electric plumbing to be done, and some person must have a working knowledge of Ohm's law, which is a law easily understood by the hydraulic engineer. Given a little motor which you can cause to revolve in either direction by setting a handle on a tram-car, it does not seem to be a troublesome thing to arrange a method of driving the car from the motor; nor is it troublesome to drive an electric launch from a motor worked by accumulators.

And yet in the early days, what high salaries we had to pay for the minimum of knowledge of electric plumbing, combined with nearly the minimum of mechanical engineering knowledge! How much trouble we had over the gearing connecting an electric motor and the wheels of a tramcar! Well, those expensive days are over—the days of advertisement and Stock Exchange success, of making bricks without straw. Various educational institutions have now given us the straw, and, as a matter of fact, we see that the best man to take charge of a system of distributing light and power is an experienced mechanical engineer who possesses a good working knowledge of the simple laws which govern electric distribution in wires. Of course, this is on the assumption that the engineer has not to construct his own dynamos and lamps, and switches and wires and motors, and accumulators and transformers. Just one year ago I impressed this on an experienced engineer who knew almost nothing about electricity. He now knows how to apply Ohm's law in all necessary ways in the large scheme which he is carrying out, and he has a better practical knowledge of electric distribution and of all the calculations to be made than any of the electricians in his employment.

When I say that the mechanical engineer ought to learn Ohm's law, I mean that he ought to pass through a proper laboratory course, and make numerical calculations in which he will illustrate all sorts of ways in which this simple-looking law is applicable. A knowledge of what is meant by amperes, volts, ohms, and watts, cannot be obtained merely by listening to lectures or by reading. Just as a little use of a watch, of a two-foot rule, and of a spring-balance give exact practical notions of the measurement of time, of distance, and of force, so the use of an ammeter and voltmeter will give exact practical notions about Ohm's law and electric measurements generally.

And now as to the construction and manufacture of electrical appliances. Given perfect working drawings of any machine or instrument, with necessary instructions, the manufacture may be carried on by the ordinary foremen and workmen of any engineering shop. If I can be sure that my instructions shall be carefully carried out, I prefer to have my work done at such a shop. Only if something is specified as charcoal iron it must not be made of Siemens steel, as, I am sorry to say, it very often is, or of malleable cast iron, as it sometimes is. If plates are shown separated by Willesden paper, then Willesden paper, and no other material, must be used. As workmen obtain more electrical information, and therefore understand better why such instructions are given, there will be more certainty of their being attended to. This manufacture may really be said to be altogether in the hands of the mechanical engineer, and if he would only try to gain what is easily gained—a working knowledge of electricity and magnetism—the design of electrical contrivances would also be in his hands; for even now many electricians are not sufficiently alive to the importance of drawing. One gentleman I know, who has designed many successful instruments and machines, followed this procedure:—He went to his instrument-maker and gave careful instructions, illustrated by sketches, as to the making of a new instrument. At the end of a fortnight he went to see the instrument as made, pointed out that it was not at all what he wanted, and gave better instructions for a second—for, indeed, his own ideas were now clearer; went again and recommended changes to be made, and again and again, sometimes seven visits, with seven radical changes, taking place before the instrument was satisfactory. It required ocular demonstration to convince him that one could have every detail exactly as one wanted it in the first instrument made to a working drawing.

I am sorry to say that I have found it impossible yet to depend upon the good mechanical draughtsman to design new electrical appliances. You may explain to him most carefully what you want, and look over his drawing half-a-dozen times, but wrong details are sure to escape your notice, and his own knowledge of electrical matters is as yet very poor. The man who designs a new electric appliance must be a good mechanical engineer, which assumes that he is himself a good draughtsman; and he must also be a good electrician, and it only leads to fitting and trying and partial failures for two men with the two qualifications to work together, each trying to supply the deficiencies of the other. The reasons for this may become more evident if I consider with you the design of some one electrical contrivance, and nothing is better for our purpose than a dynamo.

A dynamo consists of an armature wound with insulated wire, revolving in the field of a fixed electro-magnet. [The action of a dynamo was here briefly described by the help of a diagram.] You will observe that when matter of any kind moves in a magnetic field, there is an electromotive force set up, tending to produce an electric current, and to convert mechanical into electric energy. If the matter is conducting, like copper and other metals, the currents circulate locally in the conductor, the electric energy being wasted as heat. But when we know the exact laws of the phenomena, we can arrange that the currents shall be sent through metallic circuits outside the machine and utilised. If a disc of copper revolves so that the magnetic flux is sometimes at right angles to and sometimes parallel to its face, there will be a great resistance to its motion and a great waste of power, because of local or "Foucault" currents, whereas, if it revolves so that it is always edge on to the flux, there is but little waste of power. [The general arrangement of the fixed part of the machine was described, and it was incidentally mentioned that the iron parts when in a state of strain are less magnetic.] Now, the distribution of the fixed and movable iron is what Dr. Hopkinson has given us exact simple information about, and the sizes of the iron parts must be settled first. But the magnetic laws, although easily stated, cannot be understood by the designer and instinctively applied, all so simple as they seem, without a considerable amount of study and numerical calculation I will not here enter into them, but it may be mentioned that although it seems very easy, it is really not very easy to get into the way of using the centimetre (about two-fifths of an inch) as the unit of length. I have tried in various ways to avoid using this unit, but I am sorry to say that in these calculations all measurements must be taken in centimetres, and the dynamo designer must get used to thinking of distances, not in inches, but in centimetres. There is no doubt that this is a great affliction, for he still uses the inch as his unit of measurement when making calculations of strength and stiffness.

What comes very easy to the engineer is the notion of and the measurement of the efficiency of a dynamo. It is not unusual for manufacturers to distinguish between the electrical efficiency and the commercial efficiency of a dynamo. However useful the term "electrical" efficiency may be to those whose object it is to sell machines, to the engineer "the efficiency" is the useful output of electrical power divided by the mechanical power actually given to the machine.

Power is wasted in the machine, 1st, at the journals and brushes in mechanical friction; 2nd, in air friction; 3rd, in what may be called magnetic friction, and unless care is taken in properly dividing and insulating the iron and other metal of the armature to prevent induced currents circulating in it, this metal, and sometimes the metal of the fixed magnet at its pole pieces, gets greatly heated; 4th, in electric friction in the wires of the armature, because electric currents flow through them. It is, indeed, this loss of energy, or rather, the rise of temperature produced, which determines the output possible from a given size of machine; 5th, a loss due to the reversal of current continually going on in the coils of the armature as they pass the brushes. You see that I have separated these losses, and each can be measured separately; but my ability to separate them, however interesting and useful it may be, gives me no right to leave out any one of them in stating the efficiency of the machine.

Some two years ago my kind friend the editor of *The Electrician* had two beautiful wood-blocks prepared to illustrate a course of lectures of mine. It seems very easy to edit one's lectures after they have been carefully prepared; but I am sorry to say that time has not allowed me yet to fulfil my engagement. However, I will circulate among you some proofs from these blocks. In one you see how we test a motor, in the other how we test a dynamo, and without actually making such tests for yourselves, I hardly see how you can gain the exact working knowledge which the engineer ought to be possessed of. The figures shown are carefully drawn from Prof. Ayrton's arrangements at the City and Guilds Central Institution, although my students experimented with the less elaborate apparatus at Finsbury. The apparatus is always ready for use. In Fig. 1, L is a Raffard (or James Thomson or Carpentier) absorption or consuming dynamometer, whose spindle is connected with the spindle of the motor M by means of a flexible coupling. The difference between the weights in pounds, multiplied by the velocity of rubbing between the cotton belt and the pulley (that is, the circumferential velocity of the pulley) in feet per minute, divided by 33,000, is the horse-power which is being absorbed in friction. Soapy water is kept trickling from the reservoir T on the rubbing belt. With this dynamometer, or with the simpler one for small powers designed

Digitized by Google

by Prof. Ayrton and myself, the motor can be kept running for hours at the same speed, and giving out the same power all the time. An ammeter and voltmeter measure the electric power given to the motor, and there is a squeezable carbon-plate resistance in a box to vary this power.

In Fig. 2 you will observe the wonderful double-cone method of continuously varying the speed of the dynamo being tested which Prof. Ayrton persisted in employing, although I told him that it could not work, as his belts were certain to break. He was right, however, and I was wrong. Observe that the dynamo is driven through a Siemens' Dynamometer, which measures the mechanical power given to the machine ; and, of course, the electrical power given out by the machine is measured with electrical instruments.

You see, then, that in electrical transmission of power we can measure with great exactness the efficiencies of the dynamo and motor. An easy measurement, or, indeed, in most cases, an easy calculation of the resistance of the conductors between two places, enables us to make exact calculations as to the loss in transmission. In fact, a distinguishing characteristic of electric work, something which is rather absent from hydraulic work and other methods of transmitting power, is the accuracy and ease with which we can make such calculations.

You will think, perhaps, that I am dwelling too long on this matter, so I will not say anything about the way in which we can divide the total loss in either of these machines so as to get exactly the five portions referred to above. Those who are interested may refer to a Paper on "Electro-Motors" published in the *Journal* of the Society of Telegraph Engineers about seven years ago.

The Mechanical Engineer may safely be left to the problem "What is the best length and shape of the journals of a Dynamo?" Even in this, however, he will find special conditions presented to him. For example, the rotating part of a dynamo is always, or may always be made to be, well balanced. The speed is usually high, so that gyrostatic action on board ship must not be altogether neglected. Sometimes the dynamo is driven direct, and if a flexible coupling be not employed considerable pressure may be produced at the bearings ; or it may be driven by belting to its overhung pulley, and again we have to consider the pressures.

Two years ago I had careful measurements made of the diameters, lengths, and speeds of the journals of all the dynamos and motors belonging to a certain educational institute. There were twelve altogether, and they were all from well-known electrical engineers. At that time I said that large dynamos of the future would have

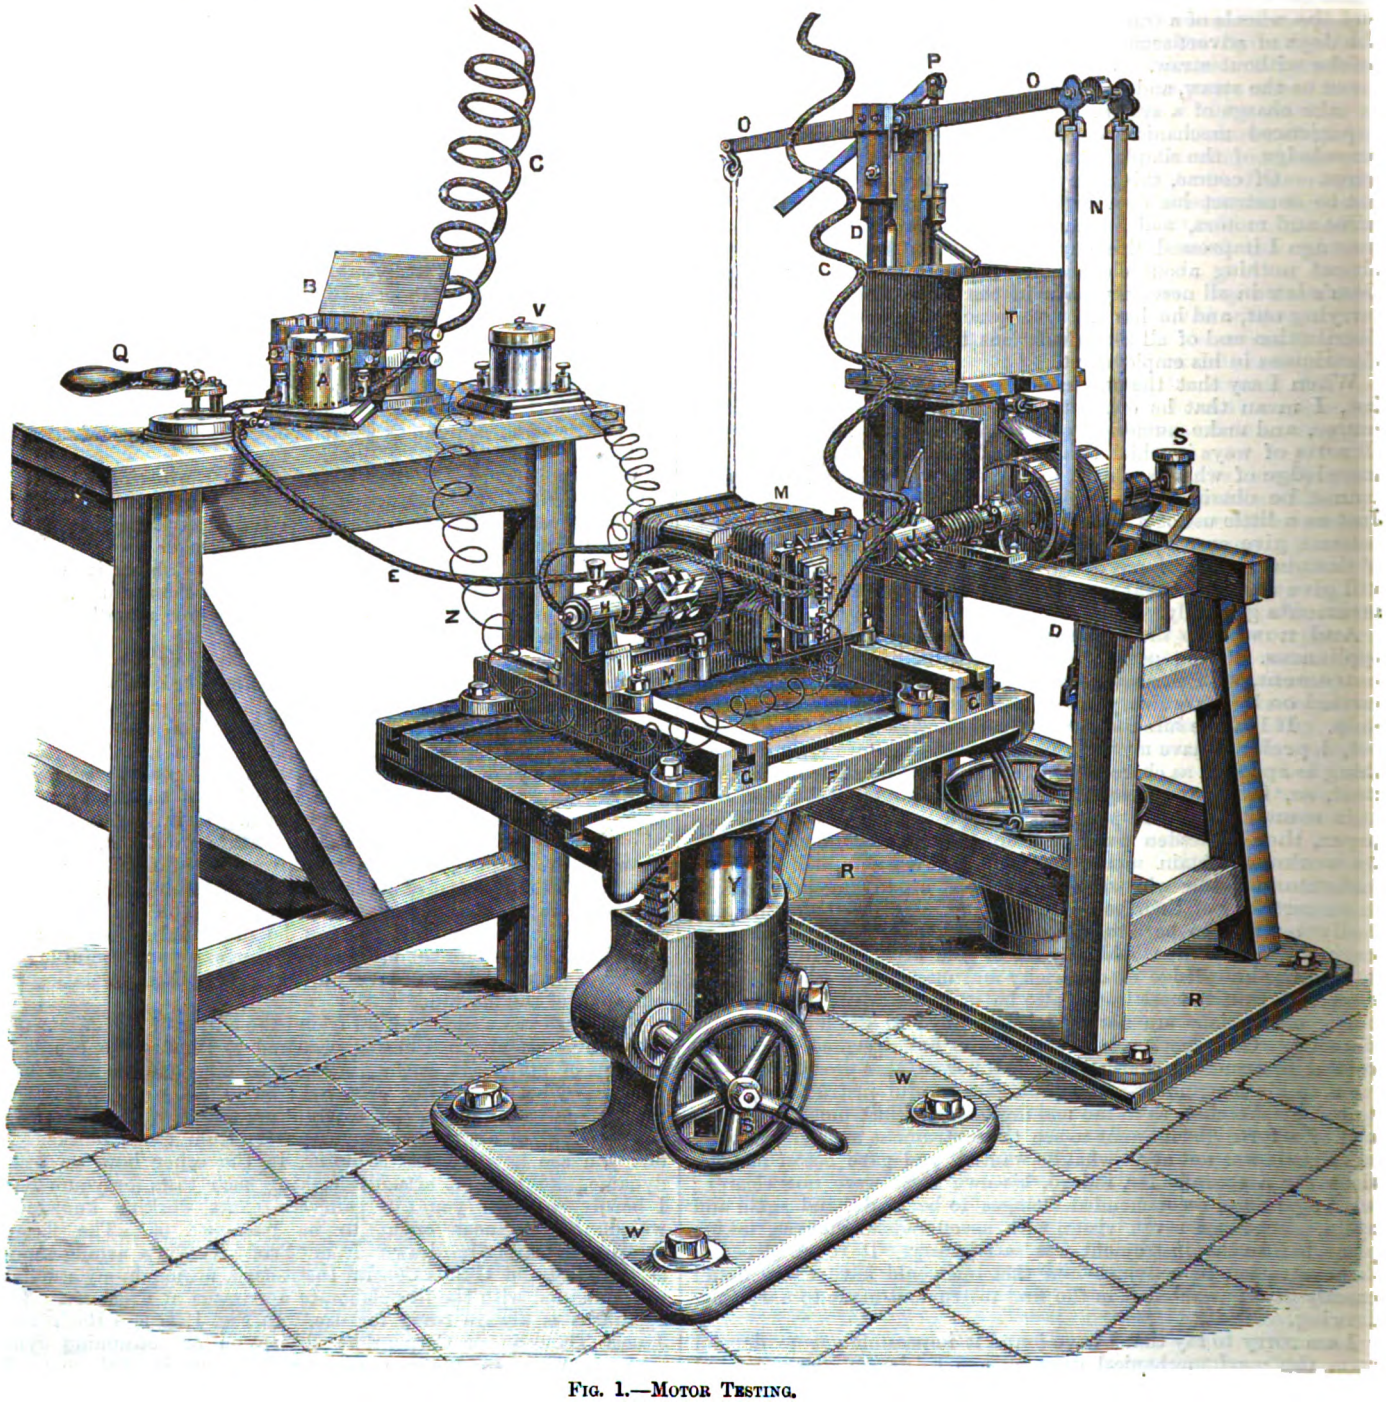

FIG. 1.—MOTOR TESTING.

Digitized by Google

roller bearings, but hitherto my prophecy has not been fulfilled. Well, I was unable to find any law connecting the dimensions and speeds and weights, not merely of the whole twelve, but even of any group of them, until I took into account a possible want of balance and spring of the spindle under centrifugal force, and then I was able to find a rule.* [*See* foot note on next page.]

It then struck me that possibly the well-known rule for ratio of length to diameter of journals in ordinary shafting, which has been found to work so well, and yet for which we have hitherto seen no reason, is really explainable on considerations of possible centrifugal force.

Then as to oiling, we have not merely to think of the necessity

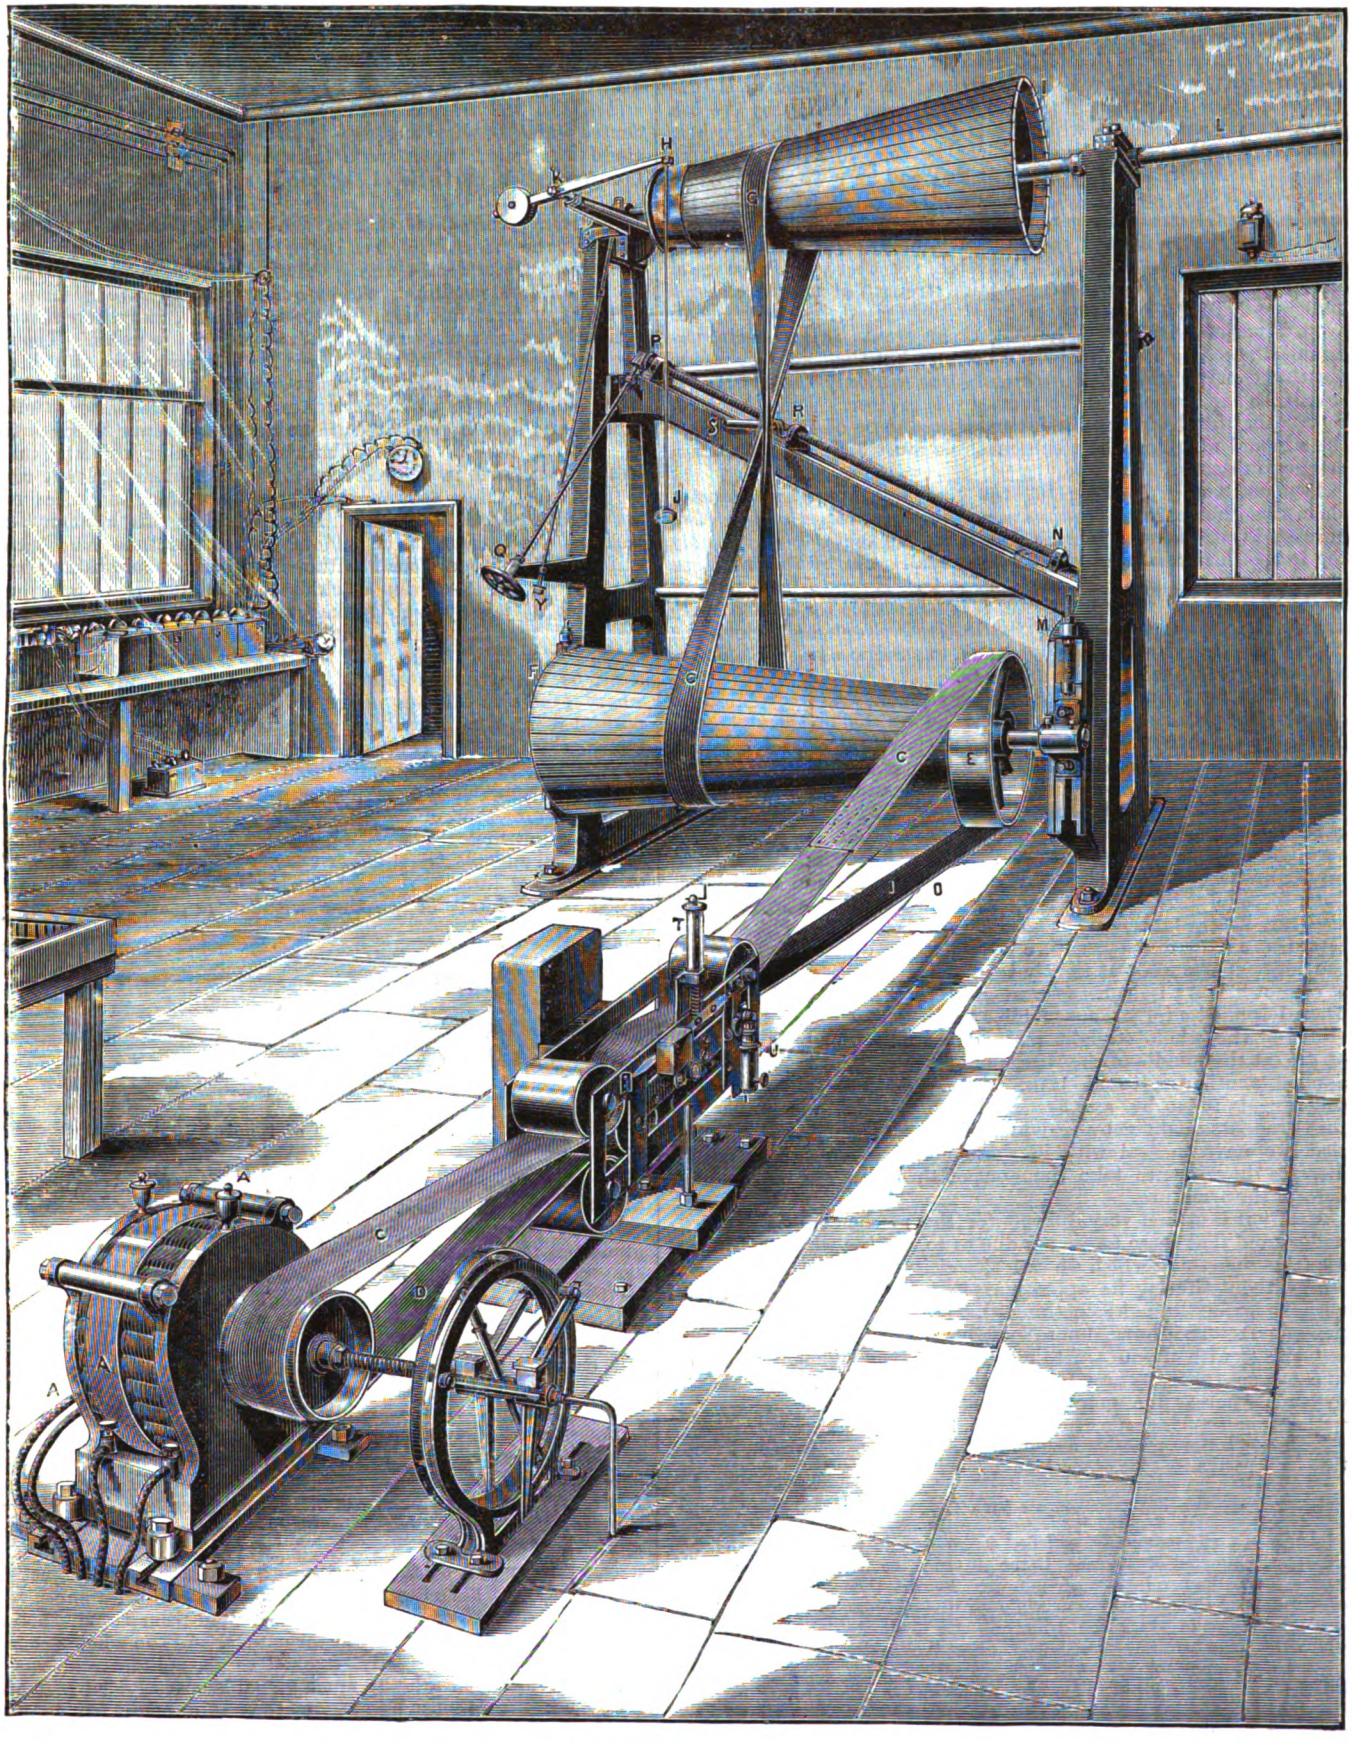

FIG. 2.—DYNAMO TESTING.

Digitized by Google

for a regular supply of oil, but of preventing this oil from penetrating the neighbouring commutator. A very little oil on the commutator surface is not objectionable, but in certain places, where there are short spaces of surface insulation, if a spark once passes through oil it may leave a carbonised residue, which destroys the electric insulation.

It is important that the dynamo should be efficient, but it is even more important that it should be *durable*. It is true that efficiency and durability go together to some extent. For example, it is difficult to imagine that a machine shall waste much energy by the 5th cause already mentioned, which leads to sparking at the brushes, or by friction at the bearings, and yet be very durable. In some respects, however, they are antagonistic ; and here we see why two men—one solely mechanical and the other solely electrical—are unable to assist one another much, and that one man must combine in himself the necessary mechanical and electrical knowledge. Everything must be as strong as possible, yet there must be good electric insulation everywhere. Again, strength of armature seems antagonistic to the necessity for great division of the iron so as to avoid Foucault currents. The electrician wants as great circumferential speed as possible in the armature, but the mechanic points out that considerations of centrifugal force will only allow of higher speeds, as the diameter of the armature is greater. The electrician retorts that for drum or cylinder armatures to be of large diameter the size and weight of the whole machine must be great, for certain magnetic reasons.

It is not merely in designing the general shape of a dynamo, then, that the engineer requires a working knowledge of the laws of magnetism, but even in such details as the method of dividing the iron of his armature so that no loss shall occur by the 3rd cause given above—that is, by Foucault currents. He must have such an acquaintance with the subject that it is impossible for him to make a mistake without experiencing that instinctive repugnance for what he has done which a good draughtsman experiences in such matters as fillets in castings and bolts and nuts.

It is difficult for us to understand why young Watt wondered at the possible pressure of steam on the lid of the mythical kettle. Yet there are many millwrights now existing who cannot comprehend the pressure of steam inside a vessel. It is in no respect more wonderful than the force which resists the motion of a wire through the magnetic field of a dynamo. Here, for example, is the copper wire of the armature of a certain dynamo. When the armature is revolving, and the proper current is flowing, there is a total force on this piece of wire, resisting its motion, of 8lb., and the centrifugal force on it is 24lb.† I remember once taking a wire of this size (2ft. long) and putting it on a piece of board shaped like the internal core part of the armature of a machine, fastening it round the edges of the wood as tightly as it is in the ordinary machine. It cannot be very tight because we must not hurt the insulation. Then I applied a force—not of 8lb., because that would be spread all over the whole straight piece of wire 2ft. long, but a force of 4lb. at the middle of the wire, pulling it sideways, and then I applied another force of 12lb. at the middle to represent the centrifugal force by another cord and weight and pulley, so that students might get a real idea of the magnitude of the forces that we have to deal with in these machines—forces trying to displace the wires, to take them out of their present position and deform the armature.

Really it is at first very difficult for the mechanical engineer to understand that these forces are due to something which he cannot see (this something which we call electricity) passing through the wire without altering its appearance in any way, and because that wire is moving through something which again he cannot see (a magnetic field). That force, due to invisible things, you will have to get acquainted with if you are to understand about dynamos and how to construct them. These forces resist the motion of the wire in a dynamo, whereas in a motor they produce the motion.

This resisting force is applied, then ceases, is applied and again ceases ; that is, it is twice applied and twice destroyed in every revolution. The average resisting force on the above wire during a revolution is only about 3lb. If you carefully study these figures you will understand why it is that the construction of an armature has become a part of mechanical engineering. Ten years ago dynamos were not very powerful, and the resisting or driving force on each piece of wire was not very great, so that the friction between insulated wire and the iron core on which it was coiled, and again, the friction between this wound core and a wooden centre which acted as a wedge in attaching the core to the spindle, could be relied upon with certainty. In modern machines, however, such methods of fastening would be childish to think of. But, difficult as it is at first to think of these resisting and driving forces on bits of wire moving through the atmosphere, the mechanic has more difficulty in comprehending how great these forces may suddenly become in an accidentally short-circuited machine. All at once the wires have, perhaps, ten or twenty times their usual greatest currents, and their motion is resisted by forces ten or twenty times as great as usual. They had been going through the atmosphere for days or weeks at a regular rate, their currents were just great enough to keep them safely warm, when suddenly ten to twenty times as much resistance to motion occurs, and heat is generated at one hundred to four hundred times as great a rate in them. Unfortunately some dynamo makers will not believe in figures like these, and when they are unable to make any other answer, they assert that their machines never are short-circuited. I assert, however, that this accident often happens, and that it is seldom that a machine has been in existence for a long time without a short circuit taking place. Happily in direct-driven machines the engine is usually pulled up—that is, the dynamo brakes the engine—and in belt-driven machines the belts slip ; but enormously increased stresses do occur for a short time, and the possibility of their occurrence must be taken into account. If this is important in dynamos, where excessive stresses occur only accidentally, think how important it must be in motors, where it may often happen that the full electric pressure is turned on even when the machine is at rest or moving slowly. I remember that, when putting up a telpher line about four years ago, I became quite desperate on account of the failure of one kind of motor after another, until at length I used the Immisch motor, which was designed by a man who combined mechanical and electrical experience. These motors have worked for years now in the charge of Sussex labourers, more or less exposed to all kinds of weather without renewal. Now, if you

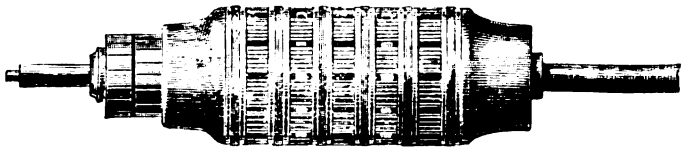

Fig. 3.—Armature of Immisch Motor

examine the armature of the Immisch motor (Fig. 3), you will see that the wires are bound down, almost covered, in fact, with many bands of phosphor-bronze wire, and that they are wound among numerous projections of iron to give the necessary strength. You can observe in the specimen I show how strong-looking these projections are. In this armature of 3in. diameter there are four iron driving discs, with altogether about forty-eight projections, each being a cube of nearly $\frac{1}{4}$in. edge. I am told by the maker that on one occasion in early days, when cast iron was used, every one of those forty-eight projections was suddenly stripped off in the natural working of a machine. Remember that the wires were bound down tightly almost the whole length of the motor with bands of fine phosphor-bronze wire, well soldered together here and there, so that the iron projections were not alone relied upon. I know of nothing which has more impressed me than this with the fact that the electrical industries require the experience of mechanical engineers.

Now, every one of these numerous copper wires is subjected to such forces as I have described, and yet no one wire must touch another metallically; they must be insulated from one another, and also from the iron core of the armature, and the whole armature must be strongly and rigidly attached to its spindle, and yet the fastenings must not take up much valuable space. I have also said that the iron core must be of numerous thin plates, which do not touch each other or the fastenings to the spindle metallically. Again, the armature must allow air to pass through it fairly well to keep the wires cool, and we must allow for local expansions and contractions by heat ; also the smaller the clearance between the revolving armature and the fixed magnet the greater is the output of the machine. [The construction of the Crompton armature was described with the help of a diagram.] I know of nothing

* Making certain probable assumptions as to want of balance, I found that for a particular type of machine

$$\overline{d} = a + b\,n\,\sqrt{L}$$

ought to be approximately satisfied in well-made machines, where l is length, d diameter of journal, L the distance between the journals in inches, and n the revolutions per minute. In the then state of dynamo construction I thought it worth while to divide dynamos into two classes only—1st, those in which the armature was drum-shaped ; 2nd, those in which the armature was disc-shaped. For the first class I found that $a=2$, $b=\frac{3}{1000}$, and for the second class $a=0$, $b=\frac{1}{1000}$, gave rules which satisfied the dimensions of the twelve machines.

† If a wire has 234 amperes passing through it and moves in the usual field of a dynamo (for those who may care to check my figures I may say that I take $\beta=7500$ C.-G.-S. units as the maximum field) we may take it that a force equal to the weight of 1lb. acts upon it per inch of its length. The force is proportional to the current and does not depend upon the velocity. Observe that it is better to calculate in this way than from the horse-power, because we want the greatest force—that is, when the wire is in the most intense field.

Digitized by Google

which requires a more general exact knowledge of the mechanical, electrical and other properties of materials, and the strength and stiffness of structures which may be subjected to local heating, than the design of the armature of a dynamo. Why, even the seventy-two fastenings of the wires to the seventy-two pieces of the commutator have been the source of much trouble, for these fastening pieces are themselves passing through some magnetic fields, and what with the magnetic resistance to their motion and their centrifugal force, and a constant vibration to which they are subjected, their arrangement presents not one but numerous new problems to the mechanical engineer, and these problems are not yet satisfactorily solved.

To describe the design of a dynamo more in detail would only weary you, so I will finish this part of my subject by referring to the commutator. Here is a nearly cylindric body. It is built up of seventy-two separate pieces, all separated from one another by thin pieces of insulating material. Not only must there be no metallic contact between piece and piece, but between any piece and the spindle to which the commutator is strongly and rigidly fastened. Now, no insulating material is very strong—it is apt to warp with heat; yet the whole structure must be strong and rigid. As it is rubbed on the outside by two metallic brushes, it is important to reduce friction by having it not too large. Some manufacturers have actually made such a commutator as this bear up against the step of the bearing, so that it should take an end-thrust, instead of putting a loose collar on the spindle. You must remember that these seventy-two pieces must all be rather deep, as they will be wearing away against their brushes for some years before they are to be renewed. Again, for the prevention of sparking the pieces ought to be of copper, but for wear, under the action of the rubbing brushes, the pieces ought to be of some material more approaching phosphor-bronze in character.

I need hardly say that the man who designs a dynamo machine ought to know something of how his design will be carried out in the shops. Again, his design will not be quite the same if only one machine is to be made as it would be if hundreds or thousands were to be made and the principle of interchangeableness of parts were to be applicable. For in this case, to take one detail, instead of casting a commutator piece of phosphor-bronze, or making experiments to find how little is the quantity of silver that one must add to copper so that a good casting of the piece may be possible, he would probably have a machine which would roll out the wedge-shaped commutator pieces in one long strip, and this would necessitate a change of design in the fastenings. His copper winding would be curiously flat in section. He would design the iron pieces of which his armature core is composed so that they might be stamped out, and he would alter his design so that the manufacturer could make large use of stamping and forging and milling machines, and in many other ways he would use his mechanical engineering knowledge for the purpose of facilitating manufacture.

You may, perhaps, think that I have dwelt too long upon my statement that an electrician must be a good mechanical engineer, or that applied electricity is merely a branch of mechanical engineering. Before Watt's time there were mechanical engineers, and when the new branch was annexed it was not called heat engineering, although all mechanical engineers were, after that period, expected to know with such exactness as was then possible the laws of heat.

Gentlemen, we are all specialists now; we devote ourselves to particular branches of our profession, but, all the time, each of us has a general knowledge of other branches of the profession. Each of you has some special knowledge, either of hydraulic machinery or stationary engines, or locomotive engines, or gas engines, or marine engines, or boiler making, or cranes and hoists, or machine tools, or some other branch of the profession. But if a man called himself a mechanical engineer who had not some general knowledge of all these branches, would you not look upon him with a certain amount of contempt? And you would be right, for the scientific principles of all the branches, and their application, and the special contrivances of all, enter often in most unexpected ways into one's own special work. The gist of this address is that the electrician has become a member of your profession. My own belief is that ten years hence he will be of as much importance in the profession as the steam-engine engineer, and that no man having a right to call himself an engineer will be without a good working knowledge of electricity; for this knowledge will give him a new weapon, which he can wield with unexampled certainty, and which, in my opinion, will develop into the most powerful weapon at his command. I could already give you many examples of the way in which a knowledge of electricity will enable you to develop your special branches of engineering, such as that of electric welding and the electric tempering of steel, and many others.

But I will end this address by asking you to put some faith in the following statement:—You know that the best steam engineers never expect to obtain more than one-tenth of the total energy of coal as actually given out by a steam engine, and that in some small engines only one one-hundredth is given out. The idea that we are wasting at an enormous rate the energy stored up for us in coal by nature during millions of years is one that sometimes becomes oppressively horrible. Now, I pointed out in 1881 that if coal or gas were burnt in a Voltaic cell as zinc is burnt, and an electro-motor were used, we could utilise as mechanical energy not merely one-tenth but nearly nine-tenths of the energy of coal. I pointed out then that coal gas could be burnt in this way, but there were two difficulties—1st, the apparatus required was too large per horse power developed; 2nd, the apparatus required was too expensive. The first of these difficulties has already been got over by a correspondent, who is in some sense my partner. We see our way to developing one useful horse-power per cubic foot of volume of apparatus. Unfortunately, the difficulty of expense still remains. But I am firmly convinced, and I have good reason for my belief, that all the difficulties will be got rid of, and that coal will actually be burnt in this way. Even to those of you who may not be troubled about the general question of economy, the mere possibility of an armour-clad being able to carry enough coal for a voyage at full speed round the world, must appear to be an important result. With the ideas of steamships carrying very much greater cargoes and going at greater speeds, and other ideas which must strike you all as the result of the above economy, I will leave you, but I must confess that the general question of economy and its influence on the progress of the race appeals to me with infinitely greater force.

ON THE PRESENT STATE OF TRACTION BY STORAGE BATTERIES.*

BY DR. LOUIS BELL.

The possibility of profitably employing storage batteries for electric traction has been a most alluring one, and during the last ten years experiments have been continually in progress toward that end. Most of these experiments have been, for obvious reasons, private, and but few definite results have ever reached the public. Reports, indeed, have been tolerably numerous of late, but in most cases all details that could possibly give a basis for an estimate of the value of the system have been omitted. Everyone now knows that a car can be propelled at a good rate of speed and up reasonable grades by means of a storage battery, but the questions to be answered are: What is the first cost and probable yearly depreciation of the batteries? What is the efficiency of the system? What is the probable cost of operation compared with horses, cables and other electrical systems?

These questions, perhaps, cannot now be fairly answered, but some recent publications give data far more valuable than anything previous; and a discussion of the general state of the problem at present is not untimely.

First, as to the efficiency of the system. It is clear from the start that the double transformation involved in the storage battery must involve a more or less serious loss of energy. The amount of this loss is easily measured in a given case; but, unfortunately, it is far from being a constant. On the contrary, it is an exasperatingly variable function of the charge and discharge rates and other minor factors. The main losses in a storage battery are due to heating, local action and electrolysis of solution, and these can never be eliminated and may be greatly increased by improper treatment of the cells.

Tested in the laboratory, at low charge and discharge rates, an efficiency of 85 to 90 per cent. is quite obtainable from most modern types of cell. But a heavy discharge rate greatly lowers the efficiency, and not only does this, but is very liable to injure the cell permanently. The same cell which gave 90 per cent. efficiency at a low discharge rate may give but 50 or 60 per cent. when discharged rapidly. There are no data available to show the efficiency of a storage battery under anywhere nearly the same conditions that exist in electric traction.

The experiments which have been made with rather heavy discharge rates seem to point to from 60 to 70 per cent. as the greatest efficiency that can be expected. But these experiments do not represent the case. In street car practice the discharge rate must be of the most variable kind, and the efficiency of a storage battery under a widely varying discharge rate has never to my knowledge been determined. It would not be sufficient to determine the amount of variation and then deduce a result from experiments at a constant discharge rate, for the effect of a heavy discharge will vary as the battery is freshly charged or partially run down.

Experiments on this subject are greatly needed. As to the efficiency of the other portions of the electrical plant information is easy to obtain.

The engine used for charging the batteries can be used rather more economically than in the electrical systems using direct

* From the New York *Electrical World*, October 5th, 1889.

Digitized by Google

supply, for it can be run, even if not under constant load, at least under one not subject to sudden and great variations.

The efficiency of the dynamo being the same in either case, and taking the friction of the engine at 10 per cent. of its rated full load, an estimate in accordance with good modern practice, the efficiency from steam to electricity at the charging station might be fairly taken at 75 per cent.

$$\frac{\text{E.H.P.}}{\text{I.H.P.}} = \cdot 75$$

The efficiency of the motors should be very nearly the same in either storage or direct systems, and for the motors in general use, the commercial efficiency, including friction of gearing, may, perhaps, be taken at 75 per cent., this figure being subject to so many varying conditions as to be rather uncertain.

Regarding the efficiency of the accumulators, I have shown that an accurate estimate cannot at present be made. At best it is very uncertain, but under the rather severe conditions imposed by traction work, I should much dislike to rely on a working efficiency greater than 70 per cent. from any accumulator with which I am acquainted.

We are now in a position to form a rough estimate of the probable efficiency of the storage battery system from indicated horse-power at the engine to wheel horse-power at the cars. Taking the above estimates, it will be:

$$\frac{\text{W.H.P.}}{\text{I.H.P.}} = \cdot 75 \times \cdot 75 \times \cdot 70 = 40 \text{ per cent. approximately.}$$

Comparing this figure with the direct supply systems, I find that Mr. G. W. Mansfield in his recent admirable Paper agrees substantially with my own estimate of the obtainable working efficiency in this case, placing it at a little under 50 per cent. for ordinary cases.

If this comparison seems unfair to the storage battery, I can only reply that I am a believer in the ultimate success of the accumulator, and would hail with joy any authentic tests disproving the above estimate.

But there is yet another side to the efficiency question that deserves careful attention. In the storage system extra power must be furnished to drag around the nearly two tons of battery. In other words, the proportion of the power furnished which goes to doing useful work is much diminished.

In fact, with any system of motors whatever, it becomes necessary, if an idea of its real efficiency is to be obtained, to take into account the effect of its dead weight on the amount of power to be furnished. There may often be good economy in sacrificing theoretical efficiency to gain practical efficiency.

To obtain a proper basis for the comparison of various motor systems we must, then, take into account the proportion of total to useful work, and to do this I have found it convenient to combine the theoretical efficiency with the ratio of useful to total work as follows:—

$$\text{Economic ratio} = \frac{\text{commercial efficiency} \times \text{useful weight}}{\text{Total weight}} = \frac{\text{E L}}{\text{W}},$$

writing E for the total commercial efficiency and L and W for the useful load and total weight respectively.

The above ratio gives a correct measure of the proportion of the power supplied to any motor system which is utilised in doing useful work. The reciprocal of the economic ratio will then be the amount of power that must be supplied to the system to do unit amount of useful work.

It measures the passenger-carrying power per horse-power furnished at the prime mover.

From the standpoint of the economic ratio it is possible to make a fair though necessarily approximate comparison between all sorts of motor systems, and to make this comparison on a common basis.

Now apply this, say, to the comparison between an ordinary electric car, a storage battery car, a cable car, and a locomotive. The total commercial efficiency should be taken as the ratio between the power generated at the prime mover and that exerted at the car wheel. The useful load should be taken in each case as the weight of the necessary car body and truck *plus* the weight of a full working load of passengers. It is clear that the car should be included, being a necessary load in each case.

Take first an ordinary electric car. A 16-foot Sprague car with two 7½ horse-power motors complete weighs about 6,400lb., of which about 2,400lb. is in motor apparatus and 4,000lb. in car. A full working load would be about 30 persons, estimated weight 4,000lb.

For a storage battery car I will take the figures of the new Julien car as far as possible. The car is stated to weigh complete 14,000lb., of which 3,800 is battery. The car has to be of unusual solidity, on account of the great weight of battery. It is a 16ft. car, and has the same carrying capacity as the above.

The cable cars are always run in trains, consisting of grip and motor cars, both carrying passengers; but as the weight of the grip apparatus is negligible, compared with the total weight, the system must be credited with an economic ratio equal to its efficiency, say, 50 per cent.

In the case of a locomotive we may take the weight of engine at 80,000lbs., tender (mean) 20,000lbs., and train of, say, four ordinary coaches, Pullman and baggage car, aggregating about 90 tons. The commercial efficiency of the system is high, since we have only to deduct engine friction, amounting to about 10 per cent. probably.

These weights are only approximations, and in any special case of course the actual weights would be substituted.

They will, however, lead to a tolerably fair comparison, and will enable some conclusions to be drawn as to the nature of the variations in the economic ratio in different systems. Computing then $\frac{\text{E L}}{\text{W}}$ we have:—

System.	Economic ratio $\frac{\text{E L}}{\text{W}}$	Power for unit useful work.
Direct electric	·385	2·62
Storage	·18	5·55
Cable	·50	2·00
Locomotive.....	·58	1·72

The economic ratio for the steam systems will increase decidedly with a heavier load, while for the electric roads it will increase, but more and more slowly as the electrical efficiency of the motors falls off. Where traffic justifies it, the use of a trailer is decidedly beneficial, evidently. The storage car seems needlessly heavy, and its economic ratio ought to be raised to ·25. The car used in Antwerp would have given an economic ratio of ·29, but it carried 1,200lb. less storage battery than the New York car.

From the inability of a storage battery to stand very heavy discharge rates, the weight of battery per horse-power hour stored is quite large. From the figures given by the Julien Company as to its New York cars, the battery has a capacity of 35 horse-power hours, and consequently weighs 108·6 pounds per horse-power hour.

It seems at present impracticable to run a car successfully and furnish the power necessary for the exigencies of the service with less than 3,000—4,000 pounds of battery. Unless the cells are very much lightened intrinsically or made capable of standing a much higher discharge rate than at present, there seems to be little hope of reducing this battery weight to a reasonable figure.

Next, as to the life that can be reasonably expected from the cells. All sorts of figures are given, but the only ones that seem to represent the real experience gained in the practical operation of a road are those recently published from the Brussels roads.* According to the result of two years' running, the positive plates would have to be renewed every 200 days. The life of the negative plates would be much longer. An American report on another type of battery used in train lighting reported positive plates destroyed within a year, and very similar experience seems to have been derived from nearly all storage batteries—out of the makers' hands. Of course with expert care continually exercised better results can be obtained. This short life makes the expenses of renewal considerable, and but little comfort can be derived from the recent suggestion that the car companies would do well to reconstruct the positive plates from the disintegrated material. From a practical point of view this is about as feasible as rewinding their burnt-out armatures and casting new trolley wheels out of the scraps of the old ones. No company of moderate size could profitably undertake this sort of work.

As to actual running expenses, the most complete figures are to be found in the Brussels report. The total expense for motive-power, repairs, renewals, &c., was 8 cents per car mile—$4.80 per car day, the run being 60 car miles.

The cost of maintaining the batteries proved to be 2¾ cents per car mile—$1.65 per car day.

The above cost of motive power was the same as with horses, while cost of plant, royalties and other expenses, brought the cost of operating with electricity considerably above that with horses. The cost of motive power, as estimated by the accumulator company was 6$\frac{4}{10}$ cents per car mile as the outside limit, while their estimate of maintenance of batteries was 1½ cents per car mile.

The estimates of the Julien Company, in New York, give motive power at $3.40 per car day of 75 miles. It is to be hoped that the ratio between estimate and fact is more favourable than on the other side of the Atlantic.

By comparison with the systems of direct supply, it is evident that, owing to lower efficiency, the expenses in actual power for the same service will be considerably (50 per cent. or so) larger in the storage system. That much is assured by the lower commercial efficiency and increased weight. Then we have maintenance of

* See *The Electrician*, August 16, p. 386.

Digitized by Google

batteries and motors, estimated by the Julien Company at $700 per car per year, as against maintenance of lines and motors in the direct supply system. The low figure on this would certainly be far below the above figure, particularly on roads of any size.

The comparison of the storage system with horse traction is not so easy. The Brussels figures are decidedly in favour of horses after two years' thorough trial. The track on that line, however, is not good, and the grades are higher than seem advisable with the storage system, there being one grade of 4 per cent. 1,500ft. long. American figures are not sufficiently definite as to details, and the favourable results have been obtained by an accumulator company's own expert care. All that can fairly be said is that it yet remains to be proved that the storage system can be operated as cheaply as horses. So long as we have to rely on the heavy and rather perishable lead accumulator, proof will be hard to obtain.

It seems to have been demonstrated that the storage system, economy aside, may be made thoroughly reliable in careful hands. The New York cars have an enviable record in this respect.

To sum up: The storage system has certain great merits which especially commend it for city work. It requires only a track; each car is an independent unit, and no accident can cripple the system. The service can be made thoroughly reliable.

Its economy is at present doubtful; it costs distinctly more than traction by direct supply and probably more than traction by horses, unless under specially favourable circumstances.

In any electric system carefully laid track is necessary for success, but in the storage system it is doubly so, and steep grades are peculiarly undesirable. There is nothing more likely to hasten deterioration of batteries than the jolting due to a rough track and the heavy discharge rates necessary on a steep grade. For city work, with good level tracks, it is certainly an ideal method of traction.

In closing, let me say that I feel confident that the time will come when the storage battery will be the general method of traction wherever the overhead wires are objectionable, and specially in large cities. The time is not yet, however, and it is by no means certain that any of the present types of accumulator will share in the ultimate success of the system.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 5, 1889.

The month of October opens with a remarkable interest in various directions in the electric railway situation. The American Street-Railway Association holds its eighth regular annual meeting on the 16th, at Minneapolis, when the attendance will be large of representative street-railway men from all sections of the country. One of the chief subjects for discussion will be "The Conditions necessary to the Financial Success of Electricity as a Motive Power." This is highly important, for with all due consideration of the other advantages to be gained from the adoption of electricity on their roads, it behoves the owners of these properties to see to it that the financial results are such as will prove satisfactory. I do not think that electricity has anything to fear whatever from a most thorough discussion and ventilation of this particular topic. Of course, it has to be borne in mind that street-railway men are not likely at any time to advertise very freely figures showing just how economically they can operate their roads, because any striking exhibition of this kind would immediately invite an attack upon them in the nature of an attempt to reduce fares. In connection with this meeting there will, of course, be an exhibition of apparatus, and the result will probably be a further increase in the number of railroads. It is already understood that the Thomson-Houston Company have secured large contracts in St. Paul and Minneapolis, but I doubt whether the roads will be in operation by that time. It is interesting to note that in connection with this meeting of the national body will be held a Convention of the Western Electric Railway Association. Electric roads are going in at such a rate in the West that it has been deemed desirable and necessary to form an organisation of this character. It has already held one meeting, and it is expected that this second one will be very interesting and valuable. That such an Association should be formed, and that material should be found for it, exemplifies in a very vivid manner the rapidity of growth in this new electrical industry, which but a year or two ago had no standing whatever except on an experimental basis. It may be remembered that last year at the meeting of the Street-Railway Association one of the members rose in his place and objected very seriously to the discussion of electrical topics, on the ground that the members did not come there to learn anything about visionary and new-fangled methods of running their cars, but to ascertain chiefly the best way to feed horses, shoe them, dispose of their manure, and sell them when old. If that gentleman, who was so eloquent a year ago in favour of the methods of the good old times happens to attend the Convention a couple of weeks hence in Minneapolis, he may be apt to find most of the members joining the electric-railway ranks, and not enough left with himself to form an Association for the advocacy of the policy of sticking to horseflesh.

It is not to be supposed that all this phenomenal development of electric railroading takes place without drawbacks and difficulties innumerable. The wonder of it is that the industry has already gone as far as it has when we consider how grave are the obstacles that have to be overcome. The electric railway companies have to be financed, for their operations are heavy, and then, of course, they have to wait a little time between the receipt of a contract, the delivery of the goods, and the going into operation of the road. We have passed beyond the day when the street railways in this country expected to have their roads equipped for nothing, simply as a return for the advertising that they gave the system; but even now there are not wanting instances in which, for the sake of stock gambling or worse, it is sought to bring discredit upon one or other of the electrical systems.

While on the subject of electric railways, in case I have not wearied your readers, I would like to mention that a very interesting analysis of the present state of traction by storage batteries appears this week in one of the electrical papers here by Dr. Louis Bell, who recently made such a valuable test of the operation of the road at Lafayette, Indiana. Dr. Louis Bell, as the result of his investigations, considers that the economy of the storage battery traction system is at present doubtful. It costs distinctly more than traction by direct supply, and probably more than traction by horses, unless under specially favourable circumstances. I need not go into the figures, which are presented in some detail, and appear to be exact; but there is one point to be borne in mind which these statistics do not bring out, and that is that the comparison between storage batteries and horses, or even between storage and direct overhead systems, has not yet been made on equal terms. By that I mean that where a horse railroad will sometimes have as many as 2,000 horses, and an overhead road will have no fewer than 40 or 50 cars, storage roads, so far, have to compile their statistics on the operation of at most three or four cars. Hence we have, so to speak, an unfair comparison of retail figures with wholesale figures, and obviously to the disadvantage of the former. This consideration comes out in a remark which Dr. Bell makes on the life of the batteries. It has been suggested that the car companies would do well to reconstruct the positive plates from the disintegrated material of the old ones. From a practical point of view, Dr. Bell says that this is about as feasible as rewinding their burnt-out armatures, or casting new trolley wheels out of the scraps of the old. He believes that no company of moderate size could profitably undertake this sort of work. That is just the point, and there is no reason why a company of something other than moderate size should not do it. A great many of the local electric lighting companies now do their repairs and reconstruction in their own workshops very economically, and there is no reason why an electric railway company, however operated, should not enjoy the same advantages. Moreover, the question arises whether we are to consider the present conditions obtaining with storage cars permanent and final, or whether we are not to expect radical improvements in the weight and capacity and durability of the batteries. Taken altogether, however, Dr. Bell's Paper is a valuable discussion of the state of affairs as we find it, and probably his suggestion as to improving the economical ratio and the means of doing so will be carefully noted and acted upon. While, as I have remarked before, the question of profit is one which street-railway men have con-

Digitized by Google

sidered as closely as anybody else in any other industry, there are incidental advantages to the principle of storage cars that must always strongly recommend them for public favour, and it is just these reasons that make the Julien cars now running in this city on the Fourth Avenue road so popular with passengers. Everybody likes to ride in them, and is willing to wait for them, skipping the intervening horse-cars.

Yet another item of street-railway news, and I will leave the subject for the present. It is worthy of note that the Brush Electric Company here have recently taken up the short series railway system, and that they are reported about to equip a road with it in Muskegon, Mich. This will be a nice little road, the equipment including four and a-half miles of new track, five new motor cars, added to the existing rolling stock, a Brush generator of 125 horse-power, and a complete station equipment. Overhead construction is to be used. It is understood that various changes and improvements have been made in the apparatus, and that under the new conditions it will have a thorough trial as to its value.

As you are probably aware, our connections with Japan are very close. The Japs are to be frequently seen on our streets and in public places, and a great many of them are actively engaged in business. Japan has been a good market for American wares, and for none more than electrical apparatus. There is a good deal of electrical lighting being done in Japan, chiefly on the Edison system, and there is a prospect of considerable advances. It cannot be said that the Japanese have shown themselves very inventive in the domain of electricity; but I have heard the remark made more than once that they show themselves remarkably skilful in their close imitations of American machinery. From time to time we are favoured with visits from Japan of representative men investigating electrical matters, and just now we have among us Mr. S. Oi, who is connected with the Japanese Government service. Mr. Oi is studying the quadruplex, as employed in this country, and proposes on his return to Japan to introduce it there, as there are some circuits upon which it can be used to advantage. Mr. Oi says that the Government is very liberal in its extension of electrical facilities, and that a large and growing telegraph business is done, especially in connection with the Stock Exchange and the rice trade. Mr. Oi states that owing to the rapid multiplication of wires the streets of Tokio in some places are like those of New York, but that there is not yet any yearning for a subway board. Mr. Oi states also, as an evidence of the interest in electricity, that the National Electrical Society of Tokio has a total of 1,015 members, most of whom are connected with the telegraph and telephone, although some, of course, are interested in the electric light. There is no doubt that Japan will continue to prove a good market for American electrical productions, and that it will not be satisfied unless it has every improvement and development that is to be found here.

Quite an interest is being taken at the present time in the system of magnetic ore-separators. This is largely due to the fact that Mr. Edison has lately been perfecting an apparatus for separating ores, and that it is now at work in various places, with what are reported to be excellent results. There is a vast amount of material offering for this kind of treatment, and there seems no reason why the application should not prove remunerative in a great many places. It is said that numerous applications are being made in the Patent Office for improvements in this field, and it may be noted that recently various patents have been issued for this class of apparatus. Among those who are thus shown to be working at the subject is the well-known physicist and electrician, Prof. W. A. Anthony, who is now connected with the Mather Electric Company.

Mr. C. E. Mitchell, Commissioner of Patents, has recently filed with the Secretary of the Interior a preliminary report of the operations of the Patent Office for the year ended June 30th, 1889. This report gives, as usual, remarkable evidence of the activity in this country in the field of invention, and particularly in the department of electricity. There were received during the year no fewer than 36,740 applications for patents, 808 applications for design patents, 101 applications for re-issues and 2,345 caveats. The number of patents granted during the year, including re-issues and designs, were 21,518, and the total number of patents granted in this country in the year reaches considerably over 400,000, of which about 300,000 are in existence and operation. With regard to the subject of legislation, the Commissioner says that some of the provisions should be altered, especially those relating to the date of patents and the duration of patents for inventions previously patented in a foreign country. Mr. Mitchell is also of opinion that the policy or practice of the patent office in adjudicating upon questions arising in regard to the granting of patents should be made to conform more nearly with the decisions of the Federal Courts. There is a great deal of trouble continually on this score, and it does not seem as if any permanent relief can be reached in the matter until definite shape is given to patent litigation by bringing it under the final review of a Patent Court established as a branch or special section of the Supreme Court of the United States. This scheme has been proposed, as you are aware, with general endorsement, and I should not be surprised to see it brought up and carried through at the next meeting of Congress.

CORRESPONDENCE.

THE DEFINITION OF IMPEDANCE AND THE PRACTICAL UNIT OF INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There would appear, from Mr. Blakesley's letter in your last issue, to be some misunderstanding as to the resolutions of the Paris Congress adopted by the Electrical Standards Committee. The three resolutions in question in his original French run as follows:—

"1. *L'Intensité Efficace* est la racine carrée du carré moyen de l'intensité du courant.

"2. *La Force Electromotrice Efficace* est la racine carrée du carré moyen de la force electromotrice.

"3. *La Resistance Apparente* est le facteur par lequel il faut multiplier l'intensité efficace pour avoir la force electromotrice efficace."

The Committee accepted the first two of these definitions. With regard to No. 3, they preferred to restrict the term "resistance" to actions purely dissipative in their nature, and adopted instead of "resistance apparente," or its exact English equivalent, the term "impedance." They have, as you point out in your Editorial Note, merely widened the meaning of the term, which had originally been restricted by its distinguished author to the case of sinusoidal currents. Some of the points raised in the discussion are given in Dr. Lodge's interesting sketch of the Electrical Papers in Section A, which appeared in your issue of October 4th.

I should like also to make a few remarks with regard to Prof. Ayrton's Paper "On the Practical Unit of Self Induction." The question seems to me to turn very much on what is meant by the word "practical" used in connection with electrical units. The term occurs, I think, originally in the first report of the Electrical Standards Committee B. A. Report, 1862 (Reprint, p. 9). Quoting a letter from Dr. Esselbach, the engineer of the Malta and Alexandria cable (the letter is given in full in the appendix), the Committee say, "Thus, his first conclusion is to adopt Weber's absolute unit substantially, and to derive from it by the multiple 10^{10} the practical unit. This practical unit is precisely that recommended by your Committee." The multiple is 10^{10}, because the fundamental unit of length employed by Weber was the millimetre. Again, Maxwell (Vol. II., § 629), on Practical Systems of Electric Units, writes:—"Thus the practical unit of resistance is called the ohm, and is represented by the resistance coil issued by the British Association and described in Art. 340. It is expressed in the electro-magnetic system by a velocity of 10,000,000 metres per second;" while, again, in 1881, the Paris Congress adopted the following resolutions (*Nature*, Vol. XXIV., p. 512):—

1. The fundamental units for electrical measurements to be the centimetre gramme and second.

Digitized by Google

2. The practical units "ohm" and "volt" to retain their present definitions—10^9 for the ohm, 10^8 for the volt.

As I understood the intentions of the Committee, the word "practical" in the definition of the electro-magnetic unit of self-induction is to have the same meaning as it has above. The absolute unit of electro-magnetic induction is the centimetre. The "practical" unit is 10^9 centimetres, and this is to be called a "quadrant." No doubt another meaning might be given to "practical"; if we interpret it as equivalent to "legal" in the term "legal ohm," then Prof. Ayrton's criticisms are justified. The legal unit of electro-magnetic measure would not be 10^9 centimetres, but somewhere about $\cdot 99777 \times 10^9$ centimetres, as Prof. Ayrton points out, but I feel sure this interpretation was not intended by the Committee.

It was felt that it was desirable to emphasise the fact that the self-induction of a simple coil in electro-magnetic measure was a quantity which could be determined with a metre scale or something equivalent to such a scale. Most observers will continue, at any rate until Professors Ayrton and Perry put their new standards of induction into the hands of electricians, to measure coefficients of induction by means of a time and a resistance. The resistance, however, was originally determined in terms of a time and a coefficient of induction calculated simply from the linear dimensions of a coil or disc. The coefficient of induction is necessarily the more fundamental quantity of the two; is it desirable to give it a name such as "secohm," which appears to derive it from its own offspring? Prof. Ayrton graduates his voltmeters in "legal" volts. Let me ask him to graduate his new Standards of Electro-Magnetic Induction in "legal quadrants."—I am, &c., R. T. GLAZEBROOK.

THE PRACTICAL UNIT OF SELF-INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Under the above title Prof. Ayrton, in your last issue, directs attention to the dilemma in which electricians have been placed by the Paris Electrical Congress and the Electrical Standards Committee of the British Association through their adoption of 10^9 C.-G.-S. units as the *practical unit* of self-induction, and to which the name "Quadrant" has been given. That 10^9 centimetres is not the practical unit is quite evident from the article above referred to, so no more need be said on that point; but it seems desirable to inquire whether anything has been gained by substituting "quadrant" for "secohm."

Perhaps some of the members of the Standards Committee can furnish conclusive arguments why the new name is preferable to the old one, but until then I venture to think that practical electricians who have to measure coefficients of self-induction will consider the change undesirable.

The name "quadrant" seems objectionable from several points of view.

First, the word already has several different meanings attached to it, *e.g.*, in geometry, gunnery, mechanism, and astronomy, and giving to it yet another meaning would be likely to lead to ambiguity. The confusion that arises from the promiscuous use of "induction" should be sufficient to condemn the use of the word "quadrant" as the name of the unit of self-induction.

Secondly, the name will serve to perpetuate error by preserving the notion that a coefficient of self-induction is a length. Of course every one knows that the dimensions of self-induction in the electro-magnetic system is L, but this result is arrived at by suppressing the dimensions of "permeability."*

It is also well known that in the electrostatic system, its dimensions are $L^{-1} T^2$, *i.e.*, $\frac{1}{\text{acceleration}}$, and therefore we could say that a coefficient of self induction is the inverse of an acceleration. That one and the same thing cannot be two totally different things seems too evident to need proof.

As an example of how one may be led into error by calculating the self induction of a coil from its linear dimensions, I may cite a case in which the *calculated* coefficient of a 10,000 ohms coil was of the order ·00003 "secohms," whereas its *measured* coefficient was 10 secohms. Thirdly, if the word quadrant is intended to suggest any well-known length (as I suppose it is), that length is the length of the earth's quadrant, and here again a discrepancy exists, for the earth's quadrant is not 10^9 centimetres, but, according to Captain Clark's determination, $1{\cdot}00074 \times 10^9$ centimetres, a difference of nearly a tenth per cent.

Fourthly and lastly, the word "secohm" has come into general use amongst those who make commercial measurements of coefficients of self-induction, and as the word is short, explicit and expressive, it would be a great misfortune to replace it by one open to such serious objections as the word quadrant.—Yours, &c., T. MATHER.

* *See* Prof. Rücker "On the Suppressed Dimensions of Physical Quantities."—*The Electrician*, Vol. XXII., pp. 108-9.

"THE A. B. C. OF ELECTRICITY."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to make a few remarks respecting the criticism of "The A. B. C. of Electricity" by Mr. W. H. Meadowcroft, contained in your issue of September 20th, 1889.

The style in which the book is written as being for children (your critic states for children of only six or eight years of age) has been to many of its older readers its great charm. There are a number of instances which have come to my attention where gentlemen largely interested financially in electric lighting, have said that this book gave them the first information they had ever been able to understand regarding the terms and general characteristics of electricity. Though the book was written primarily for children, and was originally intended to appear in the columns of a children's magazine, it was found useful to those desiring to know a little regarding electricity, and was published to satisfy a want. Mr. Edison's endorsement was one which covered merely the correctness of the statements, and was to the effect that the "treatment of the subject and arrangement of the matter have impressed me favourably." This recommendation was given by Mr. Edison as a personal favour to Mr. Meadowcroft, who had been on friendly relations with him for ten years, and was done entirely in a spirit of friendship, and after a very careful perusal of the MSS. personally, and under the advice of several of his assistants who had also read the MSS.

Your criticism specifies several cases of supposed inaccuracy. The first is the one which you quote as follows:—

"We all know that if you have a pound of water you must have something to hold it because it has weight, and consequently occupies some space. But electricity itself has no weight, and therefore cannot occupy any space."

If the words "therefore cannot" were changed to "does not" your whole criticism would fall.

The next criticism, about reckoning the pressure of water. I think that the critic would find great difficulty in putting this explanation into homely language in other phrases than Mr. Meadowcroft has used when he speaks of the pressure to the square inch of water. The moment more elaborate explanations are attempted the book would be robbed of some of its simplicity, without adding to any of its usefulness.

Regarding the criticism of the sentences which, in the words of the book, are as follows:—

"We might mention, as another analogy, the pressure of steam in a boiler, which is measured or calculated in pounds just as the pressure of water is measured. So we might say that 100 pounds steam pressure used through the medium of a steam engine to drive a dynamo, could thus be changed to electricity at 100 volts pressure."

This, Mr. Meadowcroft informs me, was suggested to him by Mr. Edison as a simple method of using the words so that an ordinary reader might understand them, and for the purpose of giving a clear example of the meaning of the word "volts."

Your next criticism is on the following sentences:—

"The only way we can get electricity to do useful work for us is to put some resistance or opposition in its way. So you see that if we make it travel through the wire around the iron or steel there is just enough resistance or opposition in its way to give it work to get through the wire, and this work produces the peculiar effect of making iron or steel magnetic."

The critic is entirely mistaken in his criticism. If he would give due weight to the word "opposition" as previously

Digitized by Google

defined in the book, he would find that Mr. Meadowcroft has given a sufficiently exact description, in a few words, of the phenomenon in question.

Regarding the criticism on Mr. Meadowcroft's description of a commutator, I would call attention to the fact that he has simply described one use of the commutator, namely, the collection of the current. He did not attempt any description of its use "to rectify the alternation of the current," as that would have been too technical for the purposes of his book.

Mr. Meadowcroft's explanation of the phenomena which occurs in the incandescent lamp is as follows:—

"You see it is a struggle between the carbon and the electricity, the current being determined to go on, and the carbon trying to keep it back, and in the end the electricity being the strongest gets the best of it; but the struggle has been so hard that the carbon has been raised to a white heat, and so gives out a beautiful light, which continues as long as the current of electricity flows."

This statement seems to me absolutely correct, and gives the phenomena in such words as can be comprehended by readers who have no technical knowledge of electricity.

I desire to protest against the criticism which is made on Mr. Edison. Mr. Edison is a man who has for many years been a hard and successful worker. I think that considering the great service which Mr. Edison's inventions have been to the world, that an electrical journal which claims to be the leading electrical journal in England should not criticise a friendly remark of his by drawing into it what ill-founded rumour gives as the gossip of the United States—namely, that he "is the inventor of electric lighting," &c.

Mr. Edison is not to blame for the fact that, having been a prolific inventor, he has been credited with more than he has accomplished. What he has accomplished entitles him, in a paper like *The Electrician*, to dignified consideration and criticism, to say the least.—Respectfully yours,

FRANCIS R. UPTON.

Orange, New Jersey, U.S.A., October 3rd, 1889.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

October 7, 1889.

15,700. W. B. SAYERS. London. Improvements in dynamo machines for electro-plating.

15,721. H. GROSSMITH. Glasgow. Improvements in electric motors.

15,733. E. DUCRETET. London. Improvements in electrical signalling apparatus.

October 8, 1889.

15,769. Sir W. THOMPSON. Glasgow. Apparatus for measuring and recording electric currents.

15,775. C. F. WINKLER. Manchester. Improvements in electro-dynamic and dynamo-electric machines.

15,819. W. F. SMITH. London. Improvements in devices for connecting the plates of one electric battery with another battery or batteries, and with a switchboard or transmitting device.

15,820. W. F. SMITH. London. Improvements in frames for supporting the plates or elements of a secondary or storage battery.

15,821. S. C. C. CURRIE. London. Improvements in the method of electrolytically reducing plates of metallic salts to a metal state to "form" the electrodes of secondary or storage batteries.

October 9, 1889.

15,840. F. H. NALDER, H. NALDER, C. W. S. CRAWLEY, and A. SOAMES. London. A new and improved meter for electric and other purposes, and for the differential actuating movement thereof.

15,848. J. A. SHELTON. London. Improvements connected with kerbings of pavements as means or apparatus for containing electric and like wires, gas, water and other pipes, or the like.

October 10, 1889.

15,936. J. ROBSON. Hanlsworth. Methods and apparatus for cleaning electric lamps.

15,958. F. W. ENGLEBACH and E. B. BRIGHT. London. A method of and appliances for preventing excessive heating or undue expansion of electric mains or surface conductors through excess of electricity, and, if convenient, utilising such excess.

15,963. P. SCHOOP. London. Improvements in the manufacture of electrodes or plates for electrical purposes.

15,967. W. C. JOHNSON and S. E. PHILLIPS. London. Improvements in insulating supports for overhead electrical conductors.

COMPANIES' MEETINGS & REPORTS.

Eastern Extension, Australasia and China Telegraph Company (Limited).

The following is the report and accounts of the Directors for the half-year ended 30th June last, to be submitted to the thirty-second ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, London, E.C., on Wednesday, the 23rd inst., at 2 o'clock:—

The gross receipts, including Government subsidies, have amounted during that period to £256,757. 3s. 2d., against £239,926. 0s. 5d. for the corresponding half-year of 1888.

The working and other expenses, including £22,626. 1s. 8d. for cost of repairs to cables and expenses of ships, absorb £73,773. 10s. 2d., against

Digitized by Google

£69,297. 10s. 11d. for the corresponding period of 1888, leaving a balance of £182,983. 13s. From this is deducted £2,652. 11s. 4d. for income tax, and £41,595 for interest on debentures and contributions to sinking funds, leaving £138,736. 1s. 8d. as the net profit for the half-year, against £125,804. 9s. 1d. for the corresponding period of 1888. Against this the Directors have charged £50,000 on account of the Western Australian Cable.

One quarterly interim dividend of 1¼ per cent. amounting to £31,250 has been paid during the half-year, and another of like amount will be distributed on the 15th instant, leaving £26,236. 1s. 8d. to be carried forward.

During the half-year under review the Saigon end of the Saigon-Hong Kong Cable has been partially renewed, and the cost of the operation, amounting to £8,092. 11s. 7d., charged against the reserve fund. Since the 30th June a further length of 127 nautical miles has been renewed, leaving only about 14 miles to complete the renewal of the shallow water portion off Saigon. This, together with the renewal of the shallow water portion of the Kong Kong end of the cable, will shortly be carried out.

The Company's maintenance ships have, as usual, been employed on various cable repairs, but no interruptions affecting the revenue have occurred during the past six months.

The South Australian Government land line between Port Darwin and Adelaide has been well maintained during the half-year under review.

The Monte Video Telephone Company (Limited).

The following is the report of the Directors of this Company to be presented to the shareholders at the annual general meeting, to be held at the offices of the Company, No. 25, Abchurch-lane, at 2 o'clock p.m. on Friday next:—

The first annual statement of accounts, made up to 31st July last, shows a profit of £10,439. 15. 10d. Off this sum there has been written £114. 14s. 8. for preliminary expenses, and £22. 2s. 9d. for depreciation of furniture, leaving a balance of £10,302. 18s. 5d. The Directors recommend that of this amount the full dividend of 6 per cent. be paid on the Preference Shares, which absorbs £7,290, leaving a balance of £3,012. 18s. 5d. which is applicable to a dividend on the Ordinary Shares. They further recommend that a dividend of 2½ per cent. be paid on the Ordinary Shares, that £1,000 be placed to renewal fund, and that the balance of £325. 8s. 5d. be carried forward. An interim dividend on the Preference Shares was paid in March last. As already notified to the shareholders, it was deemed expedient to purchase in December last the business of the Monte Video branch of the River Plate Telephone and Electric Light Company (Limited), and thus consolidate the telephone interests in that city. During the year the sum of £9,646. 18s. 9d. has been expended on capital account, in consequence of the amalgamation of the telephonic interests now under the control of this Company, and in providing the requisite plant for the most efficient telephonic service possible, such as the multiple switch-board, aerial cables, &c. This perfection of the system should result in a large accession of subscribers. In order to meet this exceptional expenditure the Directors have arranged for the issue of a portion of the unallotted capital of the Company under the powers conferred upon them. The Directors feel justified in congratulating the shareholders on the result of this first year's working, and in view of the general prosperity of Uruguay, and the arrangements they are now making for augmenting the Company's business, they feel confident of improved results in the future. In accordance with the Articles of Association, Mr. Arthur Holland retires from the Board of Directors, but, being eligible, offers himself for re-election. The auditors, Messrs. Gerard Van de Linde and Son, also retire, but offer themselves for re-election.

NORTHAMPTON ELECTRIC LIGHT AND POWER COMPANY.—A meeting of the subscribers to this company was held on Friday last, in consequence of shares not having been applied for in sufficient numbers to permit the carrying out of the original scheme. Out of 50,000 £1 shares announced in the prospectus issued a month ago, only 7,500 were subscribed for. The directors withdrew the prospectus, and proposed an alternative scheme, involving the expenditure of £10,000 only. The subscribers agreed to this and over 1,000 more shares were immediately taken up in the room.

NEW COMPANIES REGISTERED.

THE ELECTRIC ARMS AND AMMUNITION SYNDICATE (LIMITED).—This company has been registered with a capital of £40,000, in £100 shares. Objects: To enter into an agreement with the American Electric Arms and Ammunition Company to purchase certain patents and inventions. To use, develop, grant licenses in respect of or turn to account the same, and carry on any business which may be deemed directly or indirectly to benefit the company. The first subscribers are:—Major C. B. Waller, C. A. Pierce, Colonel E. Villiers, Jas. Pender, Captain J. Balfour, Major J. J. Wright, and T. Gemmell. There are to be not less than three nor more than seven directors, the first to be appointed by the subscribers to the memorandum of association.

MIDLAND ENGINEERING COMPANY (LIMITED).—This company has been registered with a capital of £100,000, in £5 shares. The object of the new company is to purchase the manufacturing rights of the Beck Gas Engine for the United Kingdom, India, Victoria, South Australia, Queensland, New South Wales, and elsewhere, and the following patents, viz., Poore, Ingrey, and Latham's rotating high-speed engine, Wansborough and Evans' safety automatic low-pressure motor, and Evans' exhaust pressure and blast fan, also the freehold property and works known as the Sandmere Engine Works, near Nottingham. Amongst the first subscribers we notice Mr. H. Sherley Price, of the well-known firm of Wheatley Kirk, Price and Goulty, 52, Queen Victoria-street, E.C. There is not to be less than three nor more than seven directors. Qualification, £500. The first directors are W. Laurence William, J. W. Restler, R. E. Commens, and R. K. Evans.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—At a meeting of the board of directors of this company held on Friday last it was resolved to declare an interim dividend for the quarter ended 30th September last of 12s. 6d. per cent. on the Ordinary Stock and 25s. per cent. on the Preferred Stock, less income-tax, payable on the 1st November to the stockholders registered on the books of the company on the 7th October, 1889.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended October 11, 1889, amounted to £3,793.

CITY OF LONDON AND SOUTHWARK SUBWAY COMPANY.—The offices of this company have been removed to the Company's City Station, 46, King William-street, E.C.

THE DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The board of directors of this company on Friday last resolved upon the payment of an interim dividend of 3s. 6d. per share, free of income-tax, being at the rate of 3½ per cent. per annum, for the quarter ended 30th September last. The dividend is payable on and after the 24th instant.

ELECTRICITY SUPPLY COMPANY FOR SPAIN.—The allotment letters to applicants for shares in this company have been posted.

THE SCHMIDT-DOUGLAS ELECTRIC COMPANY, (LIMITED).—With reference to the liquidation proceedings connected with this company, we understand it is not expected that, after paying the debenture holders, anything will be left for the trade creditors.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended October 11, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,749.

CHANGE OF NAME.—The Globe Electrical Engineering Company announce their intention to change their designation to the Globe Electrical and Art Fittings Company.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

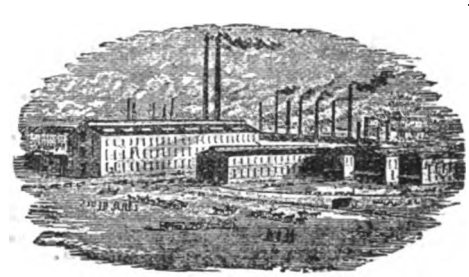
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

* No dividend since May, 1880.

JABLOCHKOFF'S

DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Wilson Hartnell.
Johnson & Phillips.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

MANVILLE & MADGEN, *Managing Directors.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 597.—Vol. XXIII. FRIDAY, OCTOBER 25, 1889. Price Fourpence.

NOTES.

By a very large majority the City Commission of Sewers on Monday last sent back for reconsideration the report of its Committee on the question of lighting the main thoroughfares by electricity. The effect of this decision will be to again delay the introduction of the electric light into the City area for a considerable time longer, probably until the several companies now applying for them have obtained statutory powers in the next Session of Parliament. No doubt by that time Mr. Sly will have satisfied himself as to the increase of illumination which the electric light would afford, while Mr. Shaw will have learnt the true value of the "new economical system" he has heard of "which could be worked without a dynamo." Lastly, the whole body of Commissioners may be brought to reflect that public convenience in the richest city of the world is not to be put off by pleas of economy which are never heard of except when the Commission has a strong bias against any project on which money has to be spent. For reasons which are not very apparent the City authorities have certainly adopted an obstructive attitude towards electric lighting. Ostensibly their present objection is mainly to the terms of the proposed contracts; but as the contractors would be only too glad to modify the conditions, we can but suppose that the real cause of opposition is kept in the background because it cannot be openly stated.

In a letter to *The Times* of Friday last, Prof. Osborne Reynolds calls public attention to the question of a national memorial to the late Dr. Joule in the following words:—

"Sir: Although the unfortunate delay which took place in publicly announcing the death of the late Dr. Joule precluded the possibility of any steps being taken to secure his interment in Westminster Abbey, it would seem fitting that a national monument should be erected to one who has secured to this country the honour of the greatest physical discovery since the time of Newton, a discovery which has produced enormous effects, material as well as scientific; and I would suggest, through your paper, that steps should immediately be taken to put in hand such a monument, and to obtain, if possible, the consent of the Dean to its erection in Westminster Abbey."

We cordially endorse the above expression of opinion. The services rendered to the cause of human progress by the classical researches of this great experimentalist ought to be commemorated in some outward and visible form. The immense revolution in human thought effected by the doctrine of the conservation of energy has only been rendered possible by researches which subjected the theory of the indestructibility of energy to the tests of an experimental scrutiny of the highest and most rigorous kind. A life-long work of this nature is not one of a character which actively affects the public imagination, but the enormous value of it can best be tested by supposing ourselves to be still living in ignorance of its results. A memorial to commemorate these splendid achievements is certainly called for. That it should be a national memorial is only fitting and right.

The results of Dr. Joule's scientific work have been digested and reproduced in so many text books and treatises that there are not many students even of an advanced knowledge who have a direct acquaintance with the original Papers themselves. They are well worth study as models of experimental researches of a quantitative nature absolutely unsurpassed in painstaking accuracy of the highest kind. In some of his investigations on the mechanical equivalent of heat, the loss of energy due to the noise made by the revolving apparatus was even estimated and allowed for by experimentally determining the work required to be done to produce an about equal sound by the movement of the bow of a violoncello across its strings. The Papers abound in striking examples of the wonderful skill, patience and inventiveness of Dr. Joule in dealing with the difficulties involved in correcting the results of observation.

The facts set forth in the lecture on "Electrical Transmission of Power in Mining Operations," recently delivered by Mr. Albion T. Snell at Wigan, which we print in another column, show very clearly that the fusion of the mechanical and the electrical engineer to which Prof. Perry alluded in his presidential address to the Junior Engineering Society is already bearing good fruit. In spite of the many unfavourable circumstances attendant on mining work, not only was the lecturer able to record a complete absence of breakdowns of the electrical plant, but he was able to show an efficiency from the engine cylinder to the pumps of considerably over 40 per cent., a result certainly due as much to good mechanical design as to sound electrical knowledge. It is interesting to notice that under precisely similar conditions the efficiency of the now discarded air plant did not exceed 14 per cent. at the best.

We publish in another column a brief account of the Slattery Alternate-Current Meter. The details of this meter which have come to hand are hardly sufficient to enable us to judge exactly wherein it differs in principle from the Shallenberger meter described in *The Electrician* of September 7th, 1888. It appears that the retarding force against which the electric

Digitized by Google

current does work is produced by the air-resistance to revolving vanes, and that, as at very high speeds this resistance varies as a somewhat higher power than that of the square of the speed, the exposed vane-surface is made to diminish automatically and reduce the resistance.

Our New York correspondent furnishes us this week with a very complete summary of the judgment, to which we alluded in our last issue, and which was recently given in the United States Circuit Court at Pittsburg, in the action brought by the Consolidated Electric Light Company against the McKeesport (Pa.) Local Edison Company, for the infringement of their Sawyer-Mann patent of 1885. The chief claim of this patent, which is owned by the Westinghouse Company, is for "an incandescing conductor for an electric lamp, of carbonised, fibrous, or textile material, and of an arch or horse-shoe shape." The Judge, it seems, narrowed down the patentable features to the fibrous filament conductor, and then decided that not only was this nothing new, but that the original intention was to secure a patent for the carbon arch. *The* great discovery, according to Judge Bradley, was the employment of a high-resistance filament. It would seem, therefore, that the first claim in Edison's (English) Patent, No. 4,516, of 1879, is as unassailable in the United States Courts as it has hitherto proved in England.

The approach of winter finds the Londoner defenceless as ever against the Fog Fiend. It is true that the County Council has appointed a Committee to consider whether anything can be done, but the question is one requiring the fullest and most competent scientific knowledge. It is, therefore, hopeless to expect that the County Councillors can provide an adequate remedy, though they may do useful work by enforcing the Smoke Abatement Act. Nevertheless, as all electricians are aware, there is some reason to think that the resources of science may yet prove adequate at least to alleviate if not to remedy the evil. The *Morning Post*, writing on the subject, suggests the appointment of a Royal Commission, consisting of specialists of the first rank, to grapple with the problem, and we would heartily endorse the suggestion. The Registrar-General's returns show that last year in London alone during three foggy weeks the deaths exceeded the average by no less than 1,400; and as for the financial aspect, it is, we believe, generally admitted that fog costs Londoners, at the very least, £2,000,000 per annum.

Amongst the many Bills which the London County Council will be responsible for in the next Session of Parliament is one dealing with overhead wires. The powers which the Council propose to obtain are only such as ought to rest with any important municipal body, and if they are administered in a proper spirit nothing but good will result, though, of course, now that all the Electric Supply Companies have been brought under stringent statutory obligations in this respect, the field of operations of the Council's Inspectors will be considerably narrowed. The removal of ownerless and the registration and inspection of the remaining wires will, however, give the Council enough to do for the present.

In *The Times* of Oct. 21 Prof. Silvanus Thompson sounds a mournful note on the subject of the possible or even actual entry of jobbery into municipal dealings in the matter of Electric Lighting. He calls to mind the indications afforded by recent gas scandals of the existence of jobbery and commission systems in the management of the gas manufacture and distribution by municipal bodies, and hopes that the newer industry of electric lighting will be preserved pure in this matter. We join heartily in the Professor's excellent wishes. Unfortunately, human nature is very much the same everywhere, but it is in the power of all of us to set a good example, and by rigidly setting our faces against any attempt to bias our own judgment in a direction contrary to the merits of the case, to create in this way a high tone which will insensibly be diffused.

Buxton.—At the last meeting of the Local Board it was agreed that any electric lighting scheme should be opposed.

The Japanese Society of Electricians.—This society, although only in existence two years, already numbers 1,015 members.

Bedford.—At the last meeting of the Town Council it was decided to take the necessary steps to secure an electric lighting Provisional Order.

Birmingham.—An accumulator car belonging to the Electric Construction Corporation was tried on the Bristol-road tramway route on Wednesday.

Obituary.—The death of M. Louis Curchod, director of the International Telegraph Bureau, at Berne, was announced in *The Times* of Monday.

York.—None of the tenders for the electric lighting of the new municipal buildings are likely to be accepted, the expense being considered too great.

Lighthouse Illumination.—Tenders will be opened on the 26th inst. at the Prefecture of La Manche for an electric light installation in the Barfleur Lighthouse.

The Van Rysselberghe System in China.—A combined telegraph and telephone line on the Van Rysselberghe system has just been finished in the North of China.

The Late Sir Daniel Gooch.—Our contemporary, the *Railway Times*, with its issue of October 18th, gave a very excellent portrait of the late Sir Daniel Gooch.

Cheltenham.—At a special meeting of the Town Council on Monday it was, after some discussion, unanimously resolved to apply for an electric lighting Provisional Order.

Croydon.—At the last meeting of the Croydon County Council, it was resolved that the Council should apply for a Provisional Order giving to the Council electric lighting powers for Croydon.

Sheffield.—At the last meeting of the Town Council it was decided to appoint a Committee to consider and report upon the desirability of applying for an electric lighting Provisional Order.

Competitions.—The Tower Company invite designs and estimates for a tower of not less than 1,200ft. in height, and offer £500 and £250 for best and second best respectively. Further particulars will be found in our advertising columns.

A Correction.—In Mr. Mather's letter on "The Practical Unit of Self-Induction," which appeared in our last issue, the following correction should be made:—Page 613, bottom line of first column, for 10 secohms read "– 10 secohms."

Glasgow.—At the last meeting of the Town Council the minutes of the Committee on Parliamentary Bills were unanimously confirmed. Among the Bills to be applied for during the next session is one giving the Corporation electric lighting powers.

Digitized by Google

Personal.—Mr. A. A. Campbell Swinton is now Messrs. C. A. Parsons and Co.'s London representative for the supply of all their manufactures. Messrs. Parsons will remove into their extensive new works at Heaton, Newcastle-on-Tyne, on the 10th November.

Marriage.—We have pleasure in recording the marriage, on the 21st inst., at Malta, of Mr. W. H. Cottrell, electrician, of the Eastern Telegraph Company, eldest son of Major W. Foulkes Cottrell, late Garrison Staff, Gibraltar, to Louise, only child of Manuel Baglietto, merchant, of Gibraltar.

Sale by Auction.—Messrs. Beal, Son and Chartres announce that (having sold the lease and furniture) they are instructed to sell on Friday next, November 1, the Electrical and Mechanical Plant belonging to the late Sir Charles Bright. Further particulars will be found in our advertising columns.

Rochester.—The Rochester Town Council have decided to adopt electric lighting for the municipal buildings, and the Vines Congregational Church, Rochester, will in future be illuminated with the electric light. This is the first place of public worship in the county of Kent to adopt the light.

The Electric Lighting of the Albert Institute, Dundee.—We hear that the installation in the Art Galleries and Libraries of this institution has proved in every way a success. The contract was carried out by Messrs. Paterson and Cooper, the engine and boiler being supplied by Messrs. Robey and Co.

The Utilisation of the Falls of the Rhine.—The syndicate which was recently formed for the purpose of utilising water-power available at the Falls of the Rhine, at Schaffhausen, hopes to commence the works at the beginning of next year, and to be in a position to distribute electrical energy in 1891.

Hull.—At the last meeting of the Works Committee of the Hull Corporation, deputations waited upon them with reference to the establishment of the electric light in Hull. The deputations were from the National Electric Supply Company, the Kingston-upon-Hull Electric Light and Supply Company, and the House-to-House Electricity Company.

The Telephone in Bolivia.—The telephone line running from Arica to Corocoro, situated in the heart of Bolivia, is probably the most elevated in the world. This line is 187 miles long, and is carried over the Andes at an altitude of 14,500ft. above the sea level. Mr. J. W. Firth, manager of the Arica and Tacna Railway, was the originator of this bold undertaking.

London County Council.—At the last meeting of the Council the report of the Highways Committee was adopted without discussion. It recommended disapproval of some proposed mains of the Westminster Electric Supply Corporation, and approval of some additional mains about to be laid by the Kensington and Knightsbridge Electric Lighting Company.

Proposed Physical Society in Liverpool.—We hear that it is proposed to form a Physical Society in Liverpool, which will hold its meetings at University College, and that Prof. Oliver Lodge has consented to be nominated as first president. A preliminary meeting will be held on November 6th. The secretary (*pro tem.*) is Mr. Thomas Tarleton, 1, Hyde-road, Waterloo, Liverpool.

Obituary.—We regret to announce the death, on Sunday, at Dinard, France, from typhoid fever, of Viscount Torrington, who was chairman from its formation of the firm of Messrs. Crompton and Co. (Limited), and also of the Crompton Electric Light Company, of Australia. Lord Torrington took a deep interest in electric lighting work, and his death is attributed largely to overwork.

Venice.—In a few months it is expected that this city will be entirely lighted by electricity, a contract to this effect having just been signed with a newly-formed company, which calls itself "The Society for the Illumination of Venice by the Electric Light." This company includes many well-known and wealthy Venetian names. The lighting up of the city is expected to be completed within four or five months' time.

The Uranium Mines (Limited).—We publish in our advertisement columns a prospectus of the above company, which, with a share capital of £120,000 in £1 shares, is formed to acquire mining rights, &c., in the county of Cornwall. Sir Alex. Armstrong, K.C.B., F.R.S., is chairman; Mr. A. J. Leese, secretary (*pro tem.*); and the offices are situate at 58, Queen Victoria-street, E.C. The lists close to-morrow (Saturday).

Baudot's Telegraph.—The success of M. Baudot's multiplex apparatus on the subterranean line between Paris and Bordeaux, with relays at Orleans, Tours, Poitiers and Angoulême, has induced the French Telegraph Administration to extend its use in this direction. The Baudot apparatus will, therefore, be shortly at work on the underground lines between Paris and Orleans-Tours, and between Paris and Poitiers-Angoulême.

Technical Education in Japan.—It is reported from Japan that Viscount Ennomoto, the new Minister of Education, is devoting special attention upon the introduction of technical education into the primary schools of the Empire, and that he has turned to Italy as a model. His scheme is to include technical education in the curriculum of the preparatory schools, and to give children technical training from the outset.

Catalogue of Electrical Apparatus.—We have received from Messrs. Ernest Scott and Co., of Newcastle, a very complete and well-illustrated catalogue of some 100 pages, giving full details of the electrical apparatus supplied by them, including dynamos (alternate and continuous-current), arc lamps, incandescent lamp fittings, cables, accumulators, measuring instruments, meters, electric bells, telephones, and a large variety of engines.

The Lighting of the Victoria Station, Bombay.—An experiment with the electric light has been recently tried at the Victoria Terminus, and proved a complete success. The result showed, says *Indian Engineering*, that the proposed change would be a vast improvement on the present gas lighting, and in keeping with the surrounding embellishments of the station buildings. The railway authorities intend introducing the change as soon as possible.

Keynsham.—The opening meeting in connection with the Working Mens' Conservative Association was the occasion of a quick piece of work on the part of Messrs. King, Mendham and Co., who were requested at a very short notice to light the public hall by electricity. A set of accumulators was telegraphed for to London, while a traction engine was secured to drive the dynamo which supplied current to the arc lights. The lighting was in every way a success.

The Edinburgh Exhibition of 1886.—The final meeting of the Association of the Edinburgh International Exhibition of 1886 was held in Edinburgh on Thursday, last week, for the purpose of winding up the Association. The total surplus stood at £5,729. 18s. 3½d., subject, however, to deductions for law charges and the expenses of winding up, reducing the amount for division to £5,447. 4s. 2d. Of this sum £2,000 was granted to Sir James Gowans, and the balance was divided amongst different scientific societies.

Import Duties in Chili.—The following information has been supplied by the Chilian Consul in London in reply to an inquiry made by the Secretary of the London Chamber of Commerce:—"I should say that electrical machinery and electric lighting apparatus imported into Chili would come under the general head of machinery, and be subject to an *ad valorem* duty of 15 per cent. Motors of any class and such-like have a fixed valuation of 25 cents per kilo. The exchange is adjusted periodically. The latest tariff I have is dated 1888, but should the interested parties to whom you refer wish to consult it, I shall be happy to allow them to do so at this office.—Chilian Consulate, 50, Old Broad street, E.C."

The Electric Light in the West.—The machinery of the Exeter Electric Light Works comprises two horizontal non-condensing compound 150 horse-power engines by Messrs. J. Fowler and Co., Leeds, driving two 4,000-light Mordey alternators. For the supply of arc lamps the Electric Light Company is using the Thomson-Houston system. There are two dynamos of this type, each capable of supplying thirty-five arc lamps of 1,200 candle-power each. These are driven by two non-condensing triple-expansion high-speed 30 horse-power

Digitized by Google

Westinghouse engines. The steam is supplied to the engines from two Babcock and Wilcox water-tube boilers, working at a pressure of 150lb. per square inch. At present there is sufficient spare power and plant to completely duplicate the whole of the lighting arrangements, and as this power is used fresh plant will be added to insure a continuous supply. The station is designed for a total capacity of 20,000 lamps.

The Edinburgh Exhibition.—We have received the prospectus of the Edinburgh Exhibition of 1890. The Exhibition, as formerly, is under the patronage of Her Majesty the Queen, and the Marquis of Lothian, Secretary of State for Scotland, is again the President. The Vice-Presidents include the Lord Provost of Edinburgh, the Lord Provost of Glasgow, and the Lord Mayor (Elect) of London, Mr. Edison, and Sir John Fowler, the engineer of the Forth Bridge. The Chairman of the Executive Committee is Sir Thomas Clark, Bart., ex-Lord Provost of Edinburgh, and of the London Committee Sir George Haytor Chubb. As we mentioned last week, the executive have secured an excellent site of about 90 acres in extent, within easy walking distance of the centre of the city, and very accessible. The promoters anticipate that the opening of the Forth Bridge early in 1890 will attract a large number of people, and these, added to the numerous visitors who annually come to Edinburgh, will no doubt ensure a success still greater than that achieved in 1886. It is proposed to close the list of applications on 1st December, 1889, the space at the disposal of the Committee being already very largely applied for.

Submarine Telegraphy—Foreign Stations.—On Saturday, the 19th inst., at the residence of Sir John Pender, Foots Cray Place, Kent, there were gathered by special invitation several managers and superintendents from foreign stations now home on leave, connected with the Eastern Telegraph Company, the Eastern Extension Telegraph Company, the Eastern and South African Telegraph Company, and the West African Telegraph Company. The localities represented were Malacca, Rangoon, Alexandria, Gibraltar, Suakim, Zanzibar, São Thomé, &c., &c. After luncheon Sir James Anderson mentioned the circumstance that the day was additionally auspicious from the fact that it was Lady Pender's birthday, and her ladyship's health was drunk with enthusiasm. Sir John Pender complimented the gentlemen present on the ability with which they had sustained their positions, and the prestige it gave to the companies over which he had the honour to preside. The excellent services rendered all round by the various staffs abroad enhanced the importance of the position he occupied. The guests were greatly struck with the beauty of the electric light installation which Sir John had established in his mansion, and which has proved perfectly successful.

Trades Section of the London Chamber of Commerce.—The following are among the agenda of the next meeting of the Committee of this Section:—1. To receive the correspondent's report. 2. To receive result of circular on B.A. screws (specimens of the B.A. screws and screwing tools will be exhibited). 3. To receive result of Standardising Laboratory circular. 4. To consider the instructions of the County Council to their surveyors, and their action in prohibiting their dispensing powers under the Metropolitan Building Act. 5. Commercial education scheme—scholarships and prizes. 6. Report of railway rates question up to date. 7. Fraudulent bills of lading—letters from Sydney Chamber of Commerce and Institute of London underwriters. 8. Dufferin banquet. 9. Trade reports and statistics. We understand that the last five items on the agenda paper for the meeting on Monday are placed there, by order of the Council, for discussion by all the Sections. Both contractors and surveyors are complaining loudly that no discretion is allowed by which the latter may permit trifling deviations from the strict letter of the Metropolitan Building Act without the sanction of that very busy body the County Council itself. This appears to be a matter which might well be entrusted to an Electric Department of the Board of Trade, together with others of a similar character.

A 2,200-Volt Shock.—In a recent number of the New York *Electrical World* Mr. L. S. Day writes as follows:—"On the evening of July 31 my dynamo attendant, Mr. D. I. Phelps, was testing a Brush arc lamp, 2,000 candle-power, which was in the circuit with 44 other lamps, said circuit and lamps being supplied by a Brush No. 8 dynamo. One of the wires became loose in the binding post of the lamp, and in his endeavour to secure it firmly it slipped from the binding post; and as he held the wire in one hand and the binding post in the other, he was put directly in the circuit with the lamps, which had a voltage of at least 2,200 volts, the station ammeter showing 9·1 amperes at the time. Mr. Phelps was thrown to the floor, but did not lose consciousness until he had raised his head from the floor to see if he was clear of the wires. He was then unconscious for two hours and twenty minutes. Bleeding at the arm and the application of a graduated Faradic current were the means used for resuscitation. Mr. Phelps is fully recovered, aside from the severe burns which he received on one hand—the one by which he held the wire—all the fingers being burned to the bone. Can it be explained how he should receive such severe burns as he did upon his tongue? The whole top surface and the edges were burned so that large blisters were formed, and yet there were no contacts made with the circuit but with the two hands."

The London County Council and Overhead Wires.—At the last meeting of the Council the Highways Committee reported that they had considered the question of overhead wires, and they recommended that it be referred to the Parliamentary Committee to prepare and introduce into Parliament in the ensuing session a Bill conferring the following powers, amongst others, upon the Council, namely—1. To compel owners of existing wires to register same, with route plan and other particulars, at the office of the Council within twelve months of the Bill becoming law, such register to be corrected annually. 2. To require, in the case of new wires, plans to be submitted for approval of Council before erection. 3. To remove ownerless wires. 4. To call upon owners to make alterations, repair defects, or renew. 5. To make by-laws and regulations as to length of span across roads and streets, height, mode of support, material and gauge of wires. 6. To authorise, in special cases, attachments to private property, subject to the question of compensation or payment by the wire owners for such privilege, and to the attachments not interfering with the free use of the property. 7. To employ inspectors. 8. To prescribe that wires be carried underground. 9. To charge a fee for annual registration.—The recommendation was approved. It was further resolved that the Council should seek for such powers in regard to subways as might be hereafter decided on.

Electric Railways in Europe.—According to a German return the number of electric railways in Europe at the end of last year was 11, of which the oldest, the Lichterfelde-Berlin Railway was opened in 1881, being 1½ miles in length, with one motor and car, and carrying yearly 100,000 passengers. The latest is that opened at Brussels last year, with five motors and cars. The other lines, their year of opening, length, and number of passengers carried by them are:—From Frankfurt to Offenbach (1884), four miles, with a maximum number of passengers in one year of 990,000; at Brighton (1883), one mile, 1,000,000 passengers in all; at Portrush (1883), six miles, 100,000 passengers a year; from Moedling to Hinterbruche (1884), 2·8 miles, 340,000 passengers; at Blackpool (1884), two miles, 300,000 passengers; at Bessbrook (1885), three miles, 300,000 passengers and 30,000 tons of goods annually; and, finally, at Hamburg, opened last year, and for which there are as yet no returns. There are besides two electric railways in Europe worked for mining purposes, viz., at Zankerode (1884), half-a-mile in length, where 17 motors and cars are used, and at Hohenzollern (1884), where, on a similar distance, 16 motors and cars are used. The working expenses on the two last-named railways, which convey 300 tons of minerals each per day, are respectively ¾d. and 1d. per ton, whereas on the passenger lines they vary from 2d. to 4½d. per car mile. In America there were 13 electric railways opened between 1885 and 1887, being on an average four miles in length. The average number of cars is six, and the number of passengers conveyed annually range from 300,000 to 400,000. It is added that at New York the working expenses worked by horses are 5½d. per mile, against 3½d. per mile when the cars are driven by accumulators.

A SINGULAR CASE OF DAMAGE BY LIGHTNING.

BY A. P. CHATTOCK.

In the afternoon of the 23rd of last May the wall of a garden in Windmill Hill, Hampstead Heath, the property of Mrs. Inman, was damaged during a thunderstorm in the manner shown in the accompanying drawing (Fig. 1), which is a copy

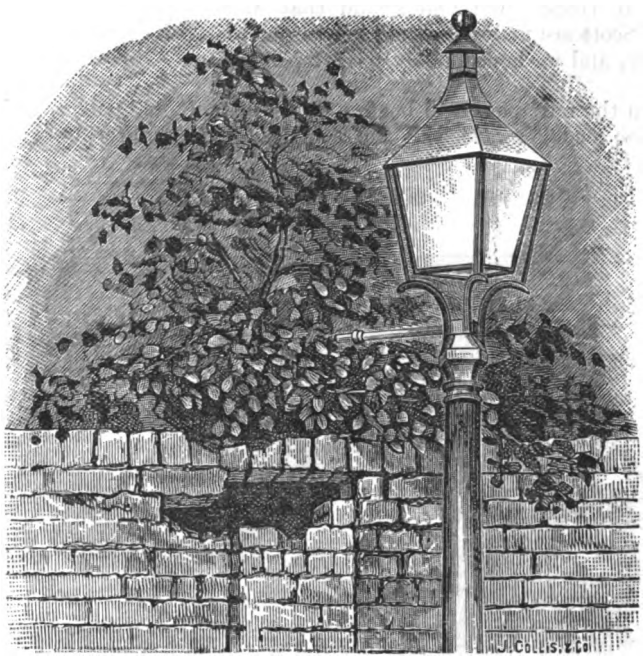

FIG. 1.

of a sketch 1 made on the spot an hour or two after the storm. The wall was completely perforated, the place chosen being at one of the buttresses, but the interesting feature of the case lies in the presence of a lamp-post just opposite, which overtops, and, owing to the narrowness of the footway, almost overhangs the wall. The actual dimensions are given in the diagram (Fig. 2).

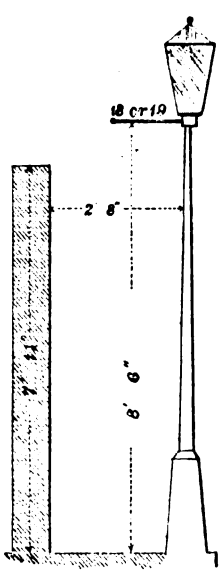

FIG. 2

According to ordinary theories the wall should have enjoyed peculiar immunity from attack at this point, yet the discharge singled out this very spot, and apparently preferred to pass through bricks and mortar under the shadow of a good conductor rather than enter the projecting end of the ladder-rest, which was not 1½ft. distant

There seems to me only one moral to be drawn from these facts, viz., that the flash was what Dr. Lodge calls an "impulsive rush" discharge; either it struck the top of the lamp-post and rebounded sideways along the ladder-rest, as such a discharge probably would, or else, which is quite possible, it entered the wall direct, without noticing the post at all. The presence of the lamp just opposite the hole inclines one rather strongly to the former view, but in opposition thereto is the fact that, so far as I could see, there was no marked indication of melting or burning at the end of the ladder-rest. Either way the case is an interesting one, taken in connection with the late discussions on the subject of discharges, and one only wishes the flash had been actually seen. That this was not the case appears from the following answers to questions, which, through the kindness of Mrs. Inman, I obtained from her gardener, who was in the garden when the accident occurred :—

1. So far as he knew, no one saw the damage done.
2. The bricks fell chiefly into the garden, *i.e.*, away from the lamp-post.
3. The damage could not have been brought about by mechanical means. The wall was in just as efficient repair there as elsewhere.
4. No metal object touched the wall, but some galvanised wire holding up the trees was very near—about 4ft. to 5ft. from the wall, attached to a tree.
5. The time of the occurrence was about a quarter to five p.m.

THE BIRMINGHAM EXHIBITION.

BRUSH ELECTRICAL ENGINEERING COMPANY.—In addition to what was said in *The Electrician*, August 9th, p. 353,

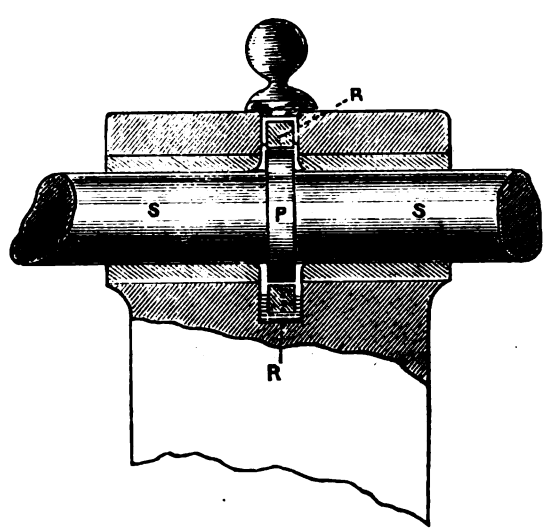

FIG. 1

describing the exhibit of the Brush Company, we give this week a description of a new method of lubricating the dynamo bearings, which somewhat resembles the contrivance adopted by the Edison Company (*The Electrician*, September 6th, p. 446). This device will be understood by reference to the figure. The armature spindle SS (Fig. 1) has a raised collar, P, turned on the spindle. On to this is loosely fitted a ring, R R, which revolves with the spindle and gathers up the oil from the cavity below, and distributes it over the spindle. To facilitate this action, a fork or prong fitted into a wooden handle is put through a hole in the cover and cut out so as to fit round the ring, as shown; it thus keeps the ring in position, and at the same time scrapes or leads off the oil on to the spindle, thus helping it to flow off more readily, the soft metal being grooved in the usual way to allow of free circulation. The company have also introduced one or two alterations in the construction of their well-known arc lamp, which enables it to be used with alternating currents. The transformers which are being used in the stand are connected

Digitized by Google

up as follows, for the purpose of obtaining the E.M.F. required by the lamps. For running the arc lamps in parallel the primary coils of two transformers are joined in series, and the secondary coils connected in parallel; for the incandescent circuits the primary coils are joined in parallel to the dynamo terminals, and the secondary coils in parallel also. At the corner of the stand there is a 24-inch projector, as supplied to the navy. The method of driving the dynamo may be noticed as being Raworth's Patent endless rope gear, which consists of one continuous rope with a single joint passing several times round the pulley and driving wheel, the proper tension being maintained by means of an adjustable pulley attached to a bracket fixed to the floor.

Laurence, Paris and Scott.—One of the centres of attraction in the Exhibition is the stand of Messrs. Laurence, Paris and Scott (Limited), of Norwich, where, amongst other things in motion, may be seen the small engine and dynamo shown in Fig. 2. The engine appears to be exceedingly well made, as it runs quite silently at 400 revolutions per minute. It has wide bearings, balanced steel crank-shaft, and Pickering governor, adjustable whilst running. The lubrication is effected, without stopping, through properly arranged oil tubes fed by cotton syphons from ordinary oil boxes. The engine drives, by means of a thin 4½in. leather belt, a small compound-wound 1,250 watt dynamo, fixed on a sliding bed-plate, and running at 1,400 revolutions per minute. Several motors of the same type as this dynamo are shown driving the machinery in motion in various parts of the Exhibition, notably one driving a silk loom, and another in a corner by the entrance to the "Winter Gardens," driving some heavy stamping and piercing machinery. These motors are all shunt-wound, and have in addition a special series-winding outside the shunt. This is only used to start the motor, when it acts as a resistance to the armature circuit and prevents an excessive current, at the same time, exciting the field magnets more quickly and more powerfully than the shunt coils alone would do. As soon as the motor is fairly started, this series winding is cut out by an ingenious magnetic switch, which also automatically introduces the series winding again after the motor has been stopped, and thus prepares for a fresh start. A circular saw bench is exhibited in combination with one of these motors, the motor spindle and the saw spindle being coupled by means of a flanged coupling, and the motor being supported by a bracket attached to the side of the saw bench. A small combination of motor and centrifugal fan on one bed-plate is also shown by this firm. The motor spindle is coupled direct to the fan spindle by a sleeve coupling, and the fan runs at something over 5,000 revolutions per minute. It is intended to furnish the blast for a small forge. Above the door of the adjoining refreshment room may be seen a still smaller motor carrying a ventilating fan, which runs quite silently, although moving a considerable volume of air. A larger ventilating plant is shown in the engine room, also a 9 kilowatt shunt-wound dynamo, and a 12 kilowatt compound-wound dynamo, the first of which supplies current to the Telpher line in the "Winter Gardens," and the second to motors and lamps in various parts of the Exhibition. The series winding in the compound machine consists of two coils, each having 28 turns of sheet copper, 4½in. wide and ·025in. thick. We understand that Messrs. Laurence, Paris and Scott are manufacturing an erg-meter with a very wide range, and we hope shortly to give particulars.

On the next page will be found the list of gold, silver, and bronze medals awarded to the electrical and engineering exhibitors, together with full particulars as to the exhibits for which these awards were made. Eleven gold, 20 silver, 5 bronze, and 7 special gold medals, or 44 awards in all, have been obtained in the electrical section, which comprised about 50 exhibitors.

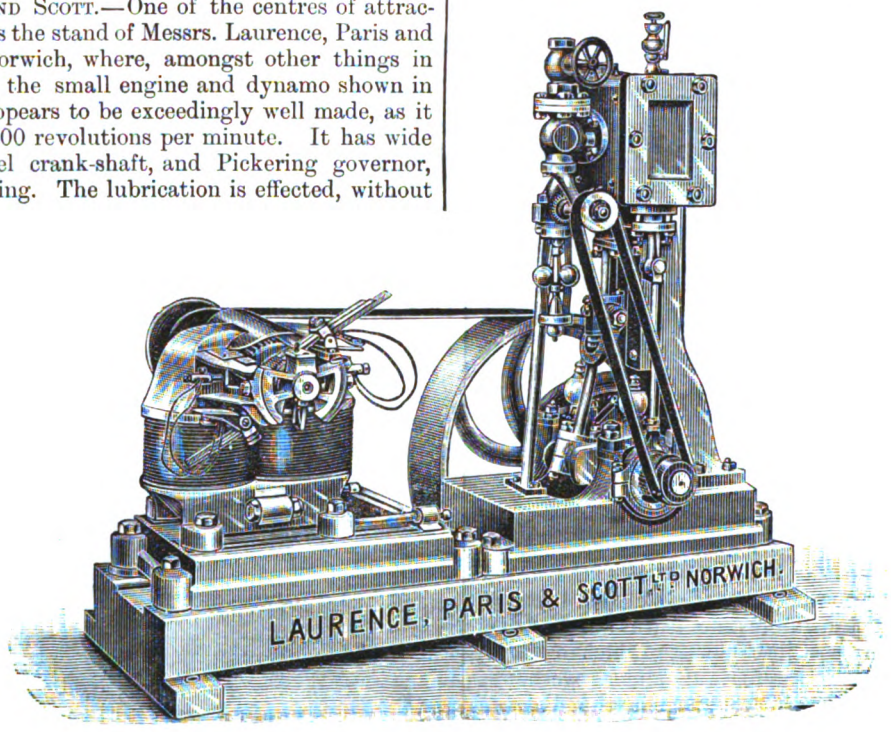

Fig. 2.

We illustrate, in Fig. 3, the design for the medals which have been awarded. The medals are in gold, silver, and bronze, and

Fig. 3.

are from the design submitted by Messrs. Jenkins and Co., Victoria-street, Birmingham. The inner part is enamelled, and the reverse side has the inscription "awarded to," &c., engraved upon it.

Piercy and Co.	Griffin Gas Engine.
Julius Sax	Electrical Fire Alarms, &c.

FIRST-CLASS BRONZE MEDALS.

Class II.—*General.*

Coad, T.....	Primary Batteries.
Conradty, C.....	Carbons.
Hartley and Co.	Electro-plating.
Myatt and Pullinger..	Ditto.
Mayfield and Co.	Wimshurst Electrical Machines.

SPECIAL AWARDS.—*Gold Medals.*

Laing, Wharton and Down	Thomson-Houston Electric Arc Lighting System
Robey and Co.	Small High-speed Engine.
Greenwood and Batley	High-speed Armington-Sims Engine.
Ruston, Proctor & Co.	Compound Engine.
Galloways (Limited)...	Boilers.

Silver Medals.

Lloyd & Co.	Mill-Shafting, Bearings, and W.I. Pulleys.
Blackman Vntilatng Co	Air Propellers.

INTERIM REPORT OF THE COMMITTEE ON "CERTAIN MOLECULAR PHENOMENA ASSOCIATED WITH THE MAGNETISATION OF IRON."*

At a meeting of the British Association at Bradford in 1873, a Paper was read by the Secretary of this Committee, and subsequently published in the *Philosophical Magazine* for December, 1873, "On Certain Remarkable Molecular Changes occurring in Iron Wire at a Low Red Heat." In this Paper the phenomenon known as the *recalescence* of iron was first published, it having been discovered by the author early in September, 1873. At the suggestion of the late Prof. Balfour Stewart, a small Committee was appointed, of which Prof. Barrett was appointed secretary, to investigate and report on recalescence and other molecular phenomena attending magnetisation. This committee had some meetings, and a good deal of unpublished experimental work was done by the secretary, but no quite satisfactory explanation of the main point, the phenomenon of recalescence, was arrived at. It was evidently not a surface phenomenon—not a mere effect of conductivity, as had been suggested—but arose from some molecular change in the metal itself. The lamented death of the two principal members of the Committee, Prof. Clerk Maxwell and Prof. Balfour Stewart, left the matter in abeyance, and the Committee lapsed before a report was presented. Recently, however, the Committee has been re-appointed, and now consists of Prof. Fitzgerald, as chairman, Mr. Trouton, Mr. Newall, and Prof. Barrett, as secretary. Owing to various causes, it is not proposed on the present occasion to do more than present a formal interim report, reserving till next year the full report of the Committee.

So much work has of late been done on the general subject of the molecular phenomena attending magnetisation that it would now be beyond the scope of the Committee adequately to report on the whole matter. We propose, therefore, in the first instance to confine our report to those phenomena accompanying the so-called critical temperature of iron—that point in, or near, which the magnetic state is lost in heating and regained on cooling. Here, at a dull red heat, a series of profound and remarkable changes occur in iron and steel, to which attention was called in the Paper referred to above. The principal points in that Paper were as follows:—

"1. Mr. Gore, in 1869, had discovered that a momentary *elongation* of iron occurred in cooling after heating a wire of that metal to a white heat. In 1873 the author found a similar but reverse action took place in *heating* the wire. 2. This anomalous deportment was found, both in heating and cooling, approximately to coincide with, on the one hand, the *loss*, and on the other, with the *resumption* of the magnetic state of iron or steel. 3. At the critical temperature the wire, having cooled down to a dull red heat, suddenly flashed into a bright glow; likewise during the *heating* of the wire the temperature remains stationary for a short time when the critical temperature is reached; a rise in the specific heat of iron and steel, therefore, occurs at the critical temperature. 4. A curious crepitating sound occurs at the critical temperature, similar to that heard in the magnetisation of iron or in the production of the scales of oxide on the wire. 5. Prof. Tait's remarkable thermo-electric change in iron occurs at this same temperature. 6. Hard iron wire and steel wire exhibit recalescence, but certain specimens of good soft iron failed to show it, and even in the wires that exhibit it the phenomenon grows less marked after repeated heating and cooling."

To these observations may be added that a recent investigation by the secretary of the Committee on the properties of 14 per cent. manganese steel wire (*Proc.* Royal Dublin Society, December, 1886) shows that this body, which is almost a non-magnetic metal, does *not* exhibit the anomalous deportment observed in ordinary steel wire. This fact is of considerable interest as linking the foregoing phenomena more closely with the magnetic state of iron and steel.

Estimating the temperature of the critical point approximately from the expansion of platinum brought to the same state of redness, it was found some years ago to be not above 800°C. The recent admirable investigations of this point by Dr. J. Hopkinson has shown it to be 680°C., rising to 712°C. during recalescence. Dr. Hopkinson has also shown that the temperature at which steel ceases to be magnetic is 690°C., so that he has definitely established the important fact of the identity of the two temperatures.

When we remember that the mechanical, electrical, and thermal properties of iron and steel are of the utmost practical importance, and that all these properties appear to undergo a remarkable change at the critical temperature, the need of a searching investigation on the question is obvious. Moreover, the interest is no less, from a theoretical point of view, in connection with theories as to the molecular structure of magnetised iron and steel.

Recalescence being feeble in soft iron, but marked in hard iron and steel, it was conjectured that the phenomenon might be

* Read by Prof. Barrett at the meeting of the British Association at Newcastle-on-Tyne, September, 1889.

Digitized by Google

due to an action, depending on the presence of carbon in iron, creating an effect analogous to that observed when water or super-saturated solutions are cooled below the solidifying point, a slight disturbance of the liquid thereupon producing a sort of explosive action, solidification occurring with a sudden rise of temperature. Prof. Roberts-Austen has drawn attention to the fact that lately M. Osmund, in France, has made recalescence the starting point of a new inquiry, tracing the effects of Carbon, Mn, Cr, S, P, and Si, on the points at which recalescence occurs or is destroyed by the alloy; that whilst *pure* iron does undergo a molecular change at a red heat, carbon retains its position as an important factor in determining the point of recalescence in hard iron and steel. Messrs. Barus and Strouhal have recently published in America a series of important Papers on the tempering of steel, and shown that a critical temperature, of between 500° and 1,000°C, exists which is intimately connected with the hardening or annealing of steel. They also draw attention to the numerous phenomena observed to occur at this temperature. Numerous other experimenters have worked at recalescence, notably Mr. Tomlinson, of King's College, and Mr. Newall, at Cambridge, but the bibliography and discussion of the whole subject will be reserved to the report next year.

DISTRIBUTION OF ELECTRICITY IN CHELSEA, &c., WITH ACCUMULATORS AS THE MAIN SOURCE OF SUPPLY.

BY MAJOR-GENERAL WEBBER, C.B.

The following is a full report of the discussion on the Paper read by Major-General Webber at the British Association:—

Mr. W. H. PREECE: I should like to ask General Webber for some further information. I am afraid he rather misled some of us by saying that the cost of feed plant for his system was 40s. per lamp; I think that wants a little modification.

Major-General WEBBER was glad of the opportunity of correcting a misapprehension into which other members of the audience might have fallen. In the estimate of 40s. only the generating and storage plant were included. The other factors differed very much according to circumstances. He thought it would be perfectly fair to say that for the total outlay in the area which he had described—giving the outside figures—about £4. 9s. 6d. should be allowed for a 30-watt lamp.

Prof. FORBES said many would agree with him that General Webber's Paper was one of the most important papers they had had on the subject of the distribution of electricity. It was not a hypothetical paper in any way, but it dealt with what had actually been done by a company, and described the first large scale application of storage batteries of the size in the way mentioned. Everyone must see from the description that had been given in the Paper that every part of the scheme had been thought out with a care which had been by no means common in all the central stations which had been designed on a new plan for the first time. In every department of the scheme, whether in the mains or in the arrangement of the batteries or in the meters, an enormous amount of thought had been put upon the details. One could see that very clearly. Consequently he thought everybody would agree that this was one of the most interesting central stations which had ever been put down, and one which would attract a great deal of attention in the immediate future—to see with what success it works, and how, financially, it comes up to the level of other central stations. There were some details he should like to speak about—not the least with the intention of criticism, but rather to draw attention to points which seemed of general interest. The first point was the system of distribution. So far as he could judge—and of course there were some details it was impossible to judge of from a written Paper—it seemed to be extremely carefully arranged, and to be very thorough indeed. There was only one point about it he did not quite understand. The feeders, charging mains, and distributing conductors were all arranged in what seemed to be an admirable way; and he hoped General Webber had introduced what was certainly a very desirable thing to introduce—varying differences of potential at the charging station of the different feeders. That in a direct system of supply was a most important thing. It also seemed very desirable to introduce counter E.M.F. cells, such as had been introduced here, when dynamos were being used, in order to adjust the pressure in the different feeders. But here he did not see what was the object of introducing counter E.M.F. cells, and perhaps General Webber would explain why he had added counter E.M.F. cells instead of simply supplying the feeders from a lower series in the scale of cells which are ordinarily in use. As to meters, he had better not say much, except that the type General Webber had described was a new modification of a system of which a good many kinds had been made on the same sort of principle; but the new type seemed to be a very ingenious arrangement. The only thing he would suggest was that where people had tried to use electro-magnetic clocks they had generally come to the manual-wound clock in the end; and he thought that in all probability as a matter of expediency that would ultimately be found desirable. On the other hand, at Berlin, where the hand-wound clocks were used very largely, they looked upon that as the chief defect of the Aron meter. One of the most interesting things in the Paper was the system with which General Webber's name was so intimately associated—that was the question of the conduits, which presented many points of interest, and in many ways were extremely convenient. The facility of manufacture was certainly very great, and it was a great thing to have a separate channel for each different conductor. When, however, it was considered that there was no attempt at insulation in the material which formed the conduits, it became a little difficult to see what was their exact object, because if they were not waterproof, and did not act in any way as insulators, their only use apparently could be as a protection for the cables, and the material being friable, and apt to break if dropped, it seemed that steam rollers and pickaxes would be apt to break it. Of course it could be easily mended. He asked whether the only advantage in the system was simply facilitating the drawing in and out of the leads. That was a very great advantage, and one which was far too much overlooked in many conduit systems; and even if that was the only advantage he should still say it was a very great one. After seeing what was being done in London at present in tearing up the streets, and the awful mess the streets were in, it was satisfactory to hear that General Webber thought he could put his thin layers of conductors under the foot pavement, occupying only a few inches of depth. Some system like that would be very largely used in the future. As to bare copper wires, they must all be very much indebted to General Webber for giving his actual experience. It has been very difficult to get actual experience from those who had used them; they were very reticent in giving the facts, even when closely pressed upon the point. The fact that he had been obliged to give this up made one think it was not so good as one had thought. He had always thought it looked very promising indeed. In one section of London where bare copper wires were being laid, they were being laid in troughs in which there were bends in a vertical plane which were not drained at the bottom of the bend. He would draw attention to what was perfectly certain to ensue from that. When water got in, which it was certain to do, it would rise up to the level of the conductors; it must, even trickling in, get decomposed for a certain time until it has decomposed away; and at the moment of breaking the contact a spark will occur and the mixed oxygen and hydrogen will undoubtedly explode. General Webber said he would not deal with financial results in his Paper, but they would all look forward with interest to a subsequent year when he would bring before them a Paper giving some of the results of the financial working, for that was really the point which was of most interest to electricians. He though every one would agree that a storage battery system was better than any other system which had ever been proposed, if the cost of the batteries and of their maintenance were sufficiently reduced. In every other way they would be superior to any system of distribution for a large number of lamps. The only financial result which General Webber had spoken about was what he had mentioned in consequence of Mr. Preece's question. It was a considerable help to be able to take it at about £4. 9s. 6d. for a 10-candle lamp That came out approximately, from comparisons with his own estimates for Paddington and other plans on the same lines for transformer work, to very nearly double what an alternating-current system would be on the whole plant, which came to about £4 or £4. 10s. per lamp of 16 candles, he thought, as a rule. A few words as to Mr. King's system of batteries. He had taken very great interest in them, and had been very pleased to see not only what was done at Colchester, but also what had been done lately at Millwall. He felt confident that Mr. King was right in believing that the whole cause of the failure at Colchester was the badness of the batteries. The batteries were very fairly good ones for that period, but they were not uniform; and it was only by having batteries of extreme uniformity that this system could be applied. The question arose whether in a sub-station where there was a large number of batteries, and where there must be an attendant looking after them—whether that attendant would be able to attend to the ordinary adjustments of pressure, and so forth. The cost of this arrangement with King's system was certainly not large, and it was extremely convenient. He had satisfied himself, not only from what he saw actually at work at Millwall, but by a careful inspection of experimental work of many months, which had been shown to him, that it was a system which would practically work extremely well; therefore if the labourer who is employed at the sub-station could do the work of this mechanism, then simply the cost of the mechanism was well worth the expenditure upon it, because the attendant would never have to supervise the mechanism, and would be relieved from a good deal of the labour.

Prof. EWING asked General Webber whether in practice he found any serious error coming into the readings of the meter he had described on account of the defects of the retentiveness of the iron core which controlled what General Webber called the integrating current. When a strong current had been sent to this meter one would expect that subsequent readings would be unduly large as compared with those readings which followed a weak current, on account of the iron core retaining a portion of its previous magnetisation.

Prof. SILVANUS THOMPSON said the meter which General Webber had described was a very interesting addition to those interesting instruments, and he believed they were all very anxious to know whether it was going to be the practical electric meter of the future. The whole subject of electric meters was one on which a great deal yet remained to be said. There was no one meter yet which had shown itself to be so far superior to the others that they could point to it and say: "That is the right thing in your house for measuring your electric consumption." The difficulty of the varying magnetic qualities of iron seemed to be got over in a most ingenious way by the introduction of the so-called integrating piece, called the cam. He asked General Webber how to find out exactly the proper shape to give that cam—is it done once for all on a certain piece of iron, or is every meter to be separately tested, and a separate cam cut for each?

Mr. W. H. PREECE said there was an immense amount of interest felt in the success or the failure of this system of the distribution of electricity

Digitized by Google

by accumulators in Chelsea—principally because the first attempt made at Colchester some years ago was a failure; secondly, because there was a most remarkable and a strange want of confidence in accumulators. He found by experience that those who had no confidence in accumulators were those who had never used them, while those who had used accumulators had very great confidence in them. He, as most of them pretty well knew, had been a staunch advocate of accumulators from their very earliest introduction into this country. Nearly six years ago his house was lighted by accumulators, and they were using them very largely in the Post Office, not only for electric lighting, but for telegraphic purposes. They had three or four hundred circuits which had been working for the last four years from accumulators. They were now introducing them for telephones. His own impression was that it was only a question of time to find the 30,000 cells in use in the Post Office in London replaced by about 300, or perhaps 1,000 accumulators. Hence the experience of accumulators was very much in their favour, and why it was that people still persisted in decrying them he could not make out. One cause was that they had been shamefully ill-used. People when they got batteries fancied that these batteries were going to do a lot for them. A great deal more was drawn out of the batteries than they were intended to give, and a great deal more current was put in them than they ought to receive. But when batteries, when accumulators, are treated fairly and properly, when they are not over-charged and when they are called upon quietly and gently—why the life of a battery is really at the present moment unknown. At the present moment he was not prepared to say that their life was more than equivalent to a renewal of about 15 per cent., but he thought in coming years, with the improvements that would arise, they would find that they would be able to maintain their batteries with probably 10 per cent.—they might even come down to 7½ per cent. of renewal. However, they would watch this experiment in Chelsea with a great deal of interest, and they would look forward at the meeting at Leeds next year to have a report from General Webber of the progress made. There was another point where he thought they would gain a great benefit, and that was from the conduits. There was one immense advantage that General Webber had over most of those electrical engineers who had been carrying out systems of distribution, and that was that he had experience of underground wires, and they had not. He did not know anything where experience was wanted so much as in the work of laying down wires underground and maintaining them. There was a terrible heresy committed in that room by Mr. Killingworth Hedges, who spoke of the relative advantages of underground wires and overground wires. He spoke as though an underground wire gave no insulation whatever, and as though the insulation of an underground system was far inferior to that of an overground system. As a matter of fact the reverse is exactly the case. Underground systems not only give a very much higher insulation, but they do very much more—they give a uniform insulation. From year's end to year's end one could rely upon the insulation of an underground system; while the insulation of an overground system is not only very low, but it is very variable and very troublesome. There was one other heresy—but it was not a heresy, it was rather want of the latest information—on the part of Mr. Hedges. That was the statement that the London Electric Supply Company were going to use mains with one conductor put to earth. Well, that was not true. There was a very delicate system used at the present moment in all our towns, and that was the system of telephone exchanges; and if such a system as that proposed to be laid down between London and Deptford were so constructed that the outside conductor were to earth, it would simply entirely upset the whole of the telephone system in London. They could not allow that, and the Government had been obliged to step in and to say that the outside conductor should not be put to earth, and something else must be provided. The result is that the main which the London Electric Supply Company are going to lay down has the outside conductor very well and very carefully insulated. It is a concentric cable; there is a solid wire in the centre, which is insulated; there is a cylinder of copper outside, which is also insulated. It is a very good conductor as far as the insulation goes, and he hoped it would answer their purposes.

Major-General WEBBER then replied to the discussion: As regarded the introduction and use of the counter E.M.F. cells, he would remind Prof. Forbes that the actual E.M.F. of each set of cells was considerably above the standard of pressure distribution required in the mains, and that these cells were destined, as it were, to control and keep down the excessive pressure acting against it at the commencement of discharge. There was a very considerable margin in having four of them, and probably more than bringing in one or two at any time as the discharge is coming to an end is not likely to occur. The question of the material in use in the conduits is one which is naturally raised, because it is unquestionable that as a material it has the defect of being friable, and that as a protection against injury when any workmen are digging in the same soil, it is not so good as tougher and harder materials. As regards steam rollers in Lennox-gardens, which is one of the squares in which a main is laid down under a Macadam surface road, the steam-roller came into operation immediately after the casing had been laid about 2ft. 6in. below the surface. He had every reason to believe that the men in charge of the steam-roller wished to put the casing to the most severe test they could. Although the earth was still loose in the trench, and although they ran the roller so that the edge of the wheel pressed down that earth and so that the weight of the roller was not distributed by being supported by the virgin earth or the solid earth each side, yet when we dug up that piece of line we found that they had not broken the casing. That was a fair test. There were other objections no doubt to the material—its porosity and its being susceptible to changes of temperature (fortunately, changes which are not very great in our climate). The adoption of the material, he thought, resulted from the effort to find one which would be economical, which could be moulded, as it were, easily, and which would permit the ways varying from three to six to pass through its interior. He saw in a late copy of one of the American papers that the Americans were doing exactly the same thing with some other plastic material; what it was he could not trace, because he had only seen an abstract of the patent. The financial results, which no doubt would be very interesting, and which ought to be perfectly reliable by this time next year, would, he thought, turn out better as to capital expenditure than the conclusion Prof. Forbes drew from the answer extracted from him by Mr. Preece. In making a comparison between two systems, it seemed to him that the only fair comparison could be on the outlay—in the case of such a system as this, on the generating plant and the storage plant, and in the case of any other systems, such as the transformer systems, on the generating plant and the transformers themselves, leaving out all questions of building, exceptional expenditure and distribution. When making that comparison, and putting it in Chelsea at 40s. or 35s., as calculated by the Storage Company for a very much larger one, he thought they would find that it was not a question of double. When he gave the total figure as £4. 9s. 6d. he included the actual figures and the actual amounts spent upon work under novel and exceptional conditions, where a building had to be erected of a much more costly nature than would be naturally the case if it could be avoided, so that he did not consider the £4. 9s. 6d. as being double the figure to be taken. As regarded the attendance at the storage stations, of course, it was quite understood that the automatic regulator is intended to avoid attendance. As to the actual amount of attendance required, it is quite certain that constant attendance while it was in use was not necessary. Their experience was that a well-instructed youth, receiving about 20s. a week, could give all the attendance necessary, not for renewal, but for the actual ordinary maintenance, to three such stations. He quite agreed with Mr. Preece's remarks on the subject of accumulators and their maintenance. He thought there was a very great probability of the actual cost of maintenance before many years being reduced to close upon 7½ per cent., as suggested by Mr. Preece. With respect to the meter, of which he had shown a rough sketch, and which was quite a new apparatus for practical use, up till now they had only placed it alongside of Aron's meter—that is to say, they had not yet entrusted to any one of these meters the sole duty of measuring the current to a customer; but in every case, and there were several, in which one of them had been placed in conjunction with an Aron meter for the purposes of experiment, the results, so far as the record was concerned, were found to be identical. There was no doubt that the residual magnetism in the regulating solenoid or the solenoid which regulates the elevation of the notch in the cam is a condition which will and should exaggerate the record. He was not prepared to say that the Aron did not do the same thing under other conditions, but so far the results had been identical. That also was the case when compared with the Chamberlain and Hookham meter. Therefore, up till now he could not say that there was any danger in using it as against the customer. The shape of the cam was produced first from a theoretical curve, but in practice every one of the cams had to be tested and the notches filed anew, so as to give an accurate result in vacuum. When saying they were all calibrated by altering the notches, that was very easily done. It was a very thin brass plate, and it was very easy to alter the notches both in length and depth by a file, and in that way before being put into use every meter was adjusted and calibrated.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

MONDAY, October 28th.

LONDON CHAMBER OF COMMERCE.

4 p.m. Meeting of the Electrical Trades' Section Committee at Botolph House, Eastcheap.

TUESDAY, October 29th.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture, "Pygmies." By Prof. W. H. FLOWER.

WEDNESDAY, October 30th.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary Meeting. Papers to be read: "On the Results of Blast-Furnace Practice with Lime instead of Limestone as Flux." By CHARLES COCHRANE. "Description of a Rotary Machine for Making Block-Bottomed Paper Bags." By JOB DUKRDIN. "Further Experiments on Condensation and Re-Evaporation of Steam in a Jacketed Cylinder." By MAJOR THOMAS ENGLISH, R.E.

THURSDAY, October 31st.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary Meeting. Papers not read at the previous Meeting.

FRIDAY, November 1st.

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, **1,** *Salisbury-court, Fleet-street, London, E.C.*

"THE ELECTRICAL WORLD" OF NEW YORK.

Arrangements have been made by which "THE ELECTRICAL WORLD" OF NEW YORK *can be obtained from* "THE ELECTRICIAN" *Office, 1, Salisbury-court, Fleet-street, London, E.C.*

The Rate of Subscription (payable in advance), is **£1 1s. 0d.** *per annum.*

Single Copies of "THE ELECTRICAL WORLD" *can also be obtained,* **price 6d. each; post free, 7d.**

"THE ELECTRICIAN" *can also be obtained of the* W. J. JOHNSTON COMPANY (LIMITED), "THE ELECTRICAL WORLD" *Office, Times Building, New York, U.S.A.*

Subscriptions are received by "*The Electrician*" *Printing and Publishing Company for all Continental and American Electrical Journals. Subscription Rates on application to* "THE PUBLISHER." *Remittance must accompany order* IN ALL CASES.

UNDERGROUND CONDUCTORS.

During the last few months any not unobservant stranger meandering about London streets must have had his attention here and there drawn to various operations and excavations in the road or footway, indicating that some process of laying down certain underground structures was in active progress. The daily Press and his own intelligent inquiries will have informed our philosopher that these operations formed the essential steps in the serious undertaking of supplying the Metropolis with distributed electric current for domestic and private electric lighting. The initiated know that these distributing constructions in the public thoroughfares are supplemented by the erection of central stations in various positions, in which the erection of steam-engines, boilers, dynamos and batteries is progressing or completed, and constituting the essential generating plant. The writers of brilliant newspaper articles, the average business man, and even the laboratory scientist, are probably inclined to direct most of their attention and interest to the generating plant. Dynamos with colossal armatures, engines of enormous horse-power, and tiers of boilers have an imposing aspect, whether in print or in reality. The difficulties involved in selecting suitable sites, in the proper design of buildings, in the arrangement of steam power, and in dynamo construction, or even in selection of the appropriate type or system of electric current generation, are serious and not small. The power to deal with these difficulties calls for engineering talent of a high order. Those persons, however,

Digitized by Google

who have had the opportunities to become acquainted with the inmost details of these enterprises in many places and under many forms are likely to direct their attention not at all exclusively to the more prominent portion of the work, but to look with a very careful eye, and to ask some very serious questions about that less showy but equally important portion of the work, viz., the distributing conductors. The erection of large steam engines and boilers is a piece of mechanical engineering so thoroughly well understood that, assuming that proper persons have been placed in charge of it, there need be no manner of doubt as to its successful completion. Dynamo building, and all the accessories of generating plant, have been also brought to such a high degree of mechanical excellence that the establishment of successful electric-current generating machinery is one in which there is not much element of uncertainty as to the performance of thoroughly good and solid workmanship when properly installed. This being so, the cautious observer may ask the question whether there is yet left any possibility of further difficulty, any room for a shadow of doubt as to the complete and immediate success of all schemes now to the front and in process of being realised for the continuous, uninterrupted, and absolutely reliable distribution of electric current in the metropolis and elsewhere.

We think that we shall not be misrepresenting the opinion of the most experienced and competent amongst the electrical engineering profession in suggesting that the question of success or failure of central-station electric lighting in its various forms is very closely bound up at the present time with the questions involved in the construction of underground conductor systems. We can take it pretty well for granted that the accumulated experience is sufficiently great to enable competent men to carry through to success many very diverse schemes for central-station generating plant. Can we also assert with equal confidence that the problem of distributing large electric currents by underground-conductors is capable of equally successful solution on a variety of different plans? In raising this question, we have no intention of suggesting that it is not the case, nor of implying that the various proposed modes of dealing with the practical difficulties of underground conductor systems have not each and all peculiar merits which recommend them in particular cases. That on which we do desire to lay stress is that the practical question of laying down in any district a network or system of subterranean insulated conductors, intended to be traversed by electric currents for lighting purposes, is one in which at the present moment there is need for the greatest caution in travelling beyond the actual limits of ascertained success. It is one in which constructions on a large scale, deviating much from that which has already, at great cost, been found to succeed, should be undertaken only after the most elaborate and careful thought. A network of conductors once laid down over an extensive area is not capable of being easily or inexpensively replaced or remodelled. The constructors of a central electric supply station, perhaps, can often more easily remedy errors of judgment in the design of the generating than in that of the distributing plant. If the next few years is to witness the establishment on a large scale of public electric supply there is no manner of doubt that the difficulties which may or will surround this important achievement will turn very largely on the wisdom and experience which are brought to bear on the design of the distributing conductor system.

In looking back at the development of electric lighting during the last ten years, it is most instructive to compare actual experience with the forecasts or expectations of those who were considered at the time to be the greatest experts. We have only to turn back to the scientific evidence given before the House of Commons Electric Lighting Committee, in May and June, 1882, and collate all that was then said about the distribution by underground conductors with subsequent facts, in order to see that not only men trained chiefly in scientific laboratory research, but practical engineers of wide experience, were absolutely unable to foresee, and powerless to anticipate, the actual difficulties awaiting solution before underground conductors could be successfully laid. Let anyone who is sceptical on this matter compare together the statements of experts on this particular point, who were called before the 1879 and 1882 House of Commons Committees on Electric Lighting, with the statements in the discussion on underground conductors which were made at the Chicago Meeting of the National Electric Light Association in 1889. In the one case we had opinions expressed with a high degree of confidence on matters as to which there was absolutely no experience; in the other we have results of experience seven years afterwards, built up on a foundation of frequent and costly failure. What, then, is the impressive lesson to be learnt from all this? Is it not the trite but still absolutely certain one that there is no road to success except that along which we are led by actual experience and in the light of previous failure? In the interests of all concerned with, and whose fortunes are bound up with the success of electric lighting, it is of paramount importance that there should be as few costly and extensive failures as possible in the enterprise of central station electric lighting.

The ground having been cleared of the chief legislative difficulties, and with the experience gained in seven years of practice and invention, the way lies open at the present time for a great extension in this country of that central electric lighting which has already taken place in other lands. But it has to be, above all things, borne steadily in mind that each and all of these enterprises depends absolutely for its financial success, and, therefore, for its continued existence, upon the complete continuity and perfect reliability of its electric current supply. We are anxious, therefore, at this time to impress upon those who are guiding the fortunes of existing central electric station schemes that no precautions are too great and no examination too elaborate in drafting the designs and settling the arrangements of that distributing conductor which is the arterial and venous system of the electric corporation, and is of as vital importance as the central organs themselves.

Has this been done as completely in all the enterprises now in progress as it is possible to do? Have all those who are responsible for the conductor systems now being laid down in London made for themselves that exhaustive and thorough examination of the methods which have succeeded and the methods which have failed as it is their duty to do? If not, then there may be a rude awakening in store which will react unfavourably upon all departments of electric engineering. The experience which has been gained in years of central station work in New York, Chicago, Boston, Milan, Berlin, is not lightly to be set aside. If, for instance, in these places experience has tended rather in the direction that copper rods, highly insulated in steel tubes filled up with a bituminous insulation, or heavily insulated cables laid in asphalte ducts or conduits, has yielded good results, may it not be, to say the least, a somewhat courageous undertaking to deviate entirely from this experience and lay down in the main thoroughfares of West London a system of iron troughs, enclosing copper strip conductors insulated only by air? We do not in any degree desire to pronounce here on the relative value of these methods. There is no reason why a system of air-insulated cables should not prove in the highest degree satisfactory, provided always that the designer of it has held in proper view such possibilities as displacement of the troughing by sinking of the roadway, and

Digitized by Google

flooding with water after prolonged rainfall, or sudden thaws after snowfall, when the ground is sodden, and when the street drainage is incapable of dealing with the accumulated water. All that we do assert is, that, in so far as it deviates from that which has been proved to succeed, it is an experiment, and may involve expensive modifications.

The establishment of the electric arterial system of London is an undertaking of considerable magnitude. We are at present in the condition when every tolerably feasible plan is being given a fair field. Each will, however, be judged severely if it is found wanting, and the survival of the fittest is a certain fact. It should be constantly borne in mind that the experience gained either of a method or a material in laying down a few hundred yards of cable is of comparatively small value in dealing with a conductor system with ramifications extending over twenty or thirty miles. And as to duration, an experience even of a year or so of the insulating durability should not be too confidently relied upon when the question at issue is the construction of an insulating system which must be practically permanent. Electric Supply Companies will not be encouraged to be everlastingly digging up the road or footway in their search for "grounds." The process of cutting out a fault or relaying a burnt-out section will necessarily involve some disturbance of public traffic. The ideal system of conductors is one laid in short lengths, each length capable of being perfectly insulated for testing, and so perfectly constructed in itself that a fault or "burn out" is of rare occurrence. We have every confidence that in time this work of electric-conductor laying will approximate to a standard type of work, and that, like the permanent way of a railway, there will be a definite method of going to work, which will embody all the best experience, and from which great deviations will not be made. It will, no doubt, also come to pass that this department of electric engineering will become specialised. There will be men who will particularly devote themselves to the accumulation of special knowledge on this subject, and contractors who will gain special experience in carrying out this work. We do not consider that in large central station work it is a good plan to commit the whole work of design from boilers to conductors to one individual. A method more conducive in the end to permanent success would be to call in the aid of those as technical advisers who have made a special study of each department. The engineer responsible for the engines and boilers is not necessarily the best man to have charge of the design of the distributing system. In railway work the locomotive engineer does not generally combine the functions of engineer of the permanent way, traffic manager, and managing director. In central electric-station work there is the same need for specialised knowledge. Before an electrical engineer undertakes to lay down a conductor system in the streets of the metropolis he ought to have had a personal and practical acquaintance with similar work in every chief city in the world in which it has been successfully laid. He ought to collate this experience, and in the light of it all to embody in his work every element of known success, and eliminate every element of known failure. He ought to take for granted nothing, and to act with the greatest caution in adopting novel methods not yet stamped with the *cachet* of success.

We are about to bury hundreds of tons of copper in the streets of London, and to transmit through them enormous electric currents. The electric engineers of to-day have in this business of constructing an electric-arterial system for great towns a work of as great, if not greater difficulty, than that of erecting the generating plant, and one in which, by the very nature of the case, it is not possible to experiment, except on a scale of twelve inches to the foot

ELECTRICAL TRANSMISSION OF POWER IN MINING OPERATIONS.*

BY ALBION T. SNELL, M.I.E.E.

Normanton Pumping and Hauling Plants.—I will first refer to a small pumping plant erected at St. John's Colliery, Normanton, in August, 1887. Mr. Warrington, of Messrs. Locke and Co., has kindly allowed me to give the following details:—The pump delivered about 39 gallons per minute through 530ft. head. A very complete test of this plant was published in the mining journals about November 18th of the same year. The results obtained were so satisfactory that Messrs. Locke and Co. decided to put down a larger plant, to deliver 120 gallons per minute, through 900ft. of vertical head, and I was entrusted with the design of the machines. This larger plant was started in February of the following year, 1888, and has continued running about 22 hours per day since then. The run now exceeds 18 months, and during that period there have been no breakdowns traceable to the electrical details, all stoppages being due to mechanical defects, incidental generally to the engine or pumps. The plant has been described before, but not in detail. I now propose to give results of tests made by the colliery engineer, Mr. E. Brown, and myself. The engine is of the semi-fixed type, by Robey and Co., of Lincoln. It is compound, and is rated by the makers at 30 nominal horse-power. It has indicated during the past 18 months on an average about 80 horse-power. The dynamo is driven off the fly-wheel by a link belt 14in. wide, curved to fit the pulley. The belt speed is about 2,750ft. per minute. The dynamo is designed to give 600 volts and 70 amperes. The motor is of similar design to the dynamo, but the field magnets are of lighter construction. The pumps are differential, with two 6in. and two 4½in. rams. The suction is made by the two large rams only. On the in-stroke the 6in. rams deliver water partly into the rising main and partly into the small rams. On the out or suction-stroke the 4½in. rams deliver into the column, and so the discharge is fairly continuous. When doing full duty the pumps make 25 revolutions per minute. The rising main is about 450 yards long, and is composed of 4in. cast-iron pipes. An air vessel about 5ft. high is fitted at the lower end, near the delivery clacks. The piping is undoubtedly too small for 120 gallons per minute. It was really designed for a feeder of about 50 gallons. The water travels in the column at about 250ft. per minute, and there is nearly 10 horse-power lost in friction. The heavy loss is against the total efficiency of the plant, and an allowance can be made if anyone thinks proper. The cable is built up of 19 strands of No. 17 B.W.G. copper wire, insulated and lead-covered. It is about 1,000 yards long and has a resistance of about ·5 of an ohm. About one week after the erection, in February, 1887, the electrical quantities for the full load averaged about 65 amperes and 603 volts, with 450 revolutions of the dynamo and 134 revolutions of the engine per minute. The motor runs at about 450 revolutions per minute, and the pumps at 25 revolutions. Under the above conditions the water delivered was measured and found to be between 118 and 120 gallons per minute. The suction has a rise of about 14ft. and the column is 860ft. in vertical height. Thus the theoretical horse-power in the water is about 32. The engine was indicated at the same time and found to be giving 80 horse-power. The efficiency of the system—that is, the ratio between theoretical work in the water and indicated horse-power of engine—was therefore equal to $\frac{32}{80}=40$ per cent. These tests have been repeated from time to time by various gentlemen, and the readings show a gradual decrease of the losses due to friction, particularly in the engine and pumps. A log has been kept, and the daily readings of current show a steady fall. At the last test, Mr. E. Brown found the current had fallen to about 62 amperes, and the engine only indicated about 73 horse-power. The efficiency had thus increased to about 43 per cent. The figures of the test are as follows:—

Work.	Volts on dynamo.	Amperes.	E.H.P. given out by dynamo.	I.H.P. of engine.	Efficiency.
Pumps running 24 revs. and delivering 117 gals. per min., 890 feet high, =31·5 H.P.	605	62	50·2	73·0	$\frac{31·5}{75}=43·1$ %
Columns run off, and suction clack lids open, engine, dynamo, leads, motor, and pumps. (Friction.)	410	27	14·8	28·6	...
Engine, dynamo, leads and motor. (Friction.)	No register.		...	18·4	...
Circuit open, engine and dynamo. (Friction.)	...	...	...	11·7	...
Belt of dynamo and engine only. (Friction.)	...	...	...	6·9	...

* Abstract of a lecture delivered in the Mining School, Wigan, September 28, 1889.

Digitized by Google

The percentage of losses, as calculated from the indicator cards, are :—

	H.-P.	Per cent.
Engine friction	= 6·9	= 9·4
Belt and dynamo friction	= 4·8	= 6·5
Leads and motor	= 6·7	= 9·4
Motor, belt, gearing, and pumps empty	= 10·2	= 14·0
Load of 117 galls. through 890ft.	= 31·5	= 43·1
Water friction in pumps and rising mains	= 12·9	= 17·6
	73·0	100

The engine doing above load indicated 73·0 horse-power. The friction of the water in the pumps and rising main is arrived at by subtracting the sum of the theoretical horse-power in the the water delivered, and the total friction, from the total indicated horse-power of the engine ; or $73=(31·5+28·6)-12·9$. This is not quite correct. The friction diagrams are necessarily taken with no load on the pumps, and hence are all slightly lower than is actually the case when the load is on. From the known efficiency of the motor, the loss in the pumps and rising main has been found to be not less than 10 horse-power. The coal consumption of this plant was so much less than that which obtained with the compressed-air plant, formerly used for the same work, that at my suggestion careful tests were made of the air-plant efficiency. The conditions were singularly favourable for comparison. The superseded air engine was still in position, and could be coupled to the same pumps. There were also two sets of compressors—a pair of horizontal compressors 20in. by 4ft., and a large vertical one. These were each put to drive the pumps, but since the pressure obtainable was only sufficient to raise the water about 530ft., the column was tapped at the Stanley Main seam. Tests of the electrical plant delivering to the same place were also made with the following results. The horizontal compressors gave a net result of 12 per cent., and the vertical one gave a little over 14 per cent. ; while the electrical system returned 44·4 per cent. The figures of the latter test are as follows :—

Work.	Volts on dynamo.	Amperes.	E.H.P. given out by dynamo.	I.H.P. of engine.	Efficiency.
Pumps running at 8 revs. and delivering 39 gals. per min. to "Stanley Main," 530 feet, = 6·3 H. P.	171·0 173·4	47·5 47·5	10·9 11·0	14·2	$\frac{6·3}{14·2}=44·4$ %
Pumps at normal speed with suction clack lids open and column run off.	128 127	28·0 26·0	4·82 4·45	6·3	...
Motor and first shaft only running approx. at normal speed.	111 105	20·0 20·0	2·96 2·80	4·8	...
Dynamo running at normal speed with circuit open.	...	...	...	1·715	...

These last tests were all made by the colliery engineer, Mr. E. Brown. The results obtained were so satisfactory that the pumps were at work only a fortnight before Messrs. Locke and Co. gave on order for a duplicate set of electrical plant, intending to use the new machines for both hauling and pumping. The pair of 20in. by 4ft. compressors were removed, and foundations were laid in their place for the two dynamos ; the old air-compressing engines 20·5in. by 4ft. being arranged by suitable gearing to run them. At the same time a set of three-throw rams, 6in. bore by 12in. stroke, were specially designed for dealing with the water. This new plant was nearly all finished and delivered at the colliery by the early part of the present year, but press of circumstances prevented the starting of the engines till late in July. The new dynamo, motor, and pumps show a further decrease of power for the same work. The quantities average about as follows :—Engine, 50 revolutions per minute; dynamo, 480 revolutions per minute, 690 volts, and 59 amperes; motor, 450 revolutions per minute; pumps, 34 revolutions per minute; water delivered about 125 gallons per minute. The arrangement of the motor house is very complete. A main shaft is run through the three houses containing the two pumps and the hauling gear. This shaft is fitted with clutches, so that either motor can be coupled to either of the pumps or the hauling sheaves ; or both motors can be coupled to the shaft, and all or any of the machines attached. It is a most convenient and efficient arrangement, and prevents a trivial accident resulting in a serious stop to the mine. The following are the particulars of the endless rope haulage: — The main or belt rope makes three turns round the main driving sheave, and then, passing round a tightening sheave, is led through a short tunnel to the main road. Here it gives motion to two horizontal sheaves, making about two and a-half turns round each. These sheaves are coupled to two endless ropes by friction cones worked by screw gear. The main rope is kept running at the desired speed, and the two working ropes are started and stopped as necessary. The main rope is one inch in diameter. The working ropes are both three-quarters of an inch. They are all made of crucible steel. The sheaves are all about 4ft. 4in. in diameter over the iron lagging. The coal now delivered is about 400 tons per day of 8 or 10 hours, the "Haighmoor" rope only being used. The motor is running at about half the arranged speed, and is doing less than half its designed output. The "Kirkthorpe" rope will be put on next week. Even with this additional load of some 300 tons per day there is an ample margin for future increase of output. The arrangement could easily deliver 1,000 to 1,200 tons per day if necessary. No difficulty of any kind has been experienced with the hauling details. The ropes work with the regularity of clockwork, maintaining an almost constant speed whatever the load may be. The dynamo and motor are running most satisfactorily ; indeed, without looking at the ammeter it is hardly possible to say whether the working rope is on or not.

Llanerch Colliery Hauling and Pumping Plant.—As an example of electricity applied to drive a single-rope hauling engine, I will refer to a plant at Llanerch Colliery, near Pontypool, Monmouthshire. This plant has now been in use for about four to five months. By the courtesy of the owners, Messrs. Partridge and Jones, I am enabled to give the following particulars :—The dynamo is driven by a horizontal engine with an 18in. cylinder and 3ft. 6in. stroke, making at full speed about 50 revolutions per minute. The steam pressure varies between 60lb. and 50lb. at the main boilers, and the speed is controlled by a Pickering governor. The engine drives a countershaft by a 9in. by ¾in. link belt, and the dynamo is run off this shaft by a similar but lighter belt. Provision is made for running a second dynamo for lighting and other purposes. The engine-house is built with sandstone quarried on the spot. The pit shaft is 250 yards deep, and the motor-house is about 750 yards in-bye on the main in-take. The copper cable is composed of 19 strands of No. 18 B.W.G., insulated and covered with lead. The shaft is rather wet, and the roads are also damp ; but no special trouble has been caused by this. The roofs and sides are not particularly good. The "falls" have caused some trouble with the cable, but it is fully expected that the arrangements now made will meet the case. The motor is coupled to a counter-shaft on the hauling-engine bed by a link-belt. A pinion on this shaft engages a wheel mounted on the drum axis. The drum is thrown out of gear by a lever to let down the empties, as is usual with single-rope haulage. In fact, the haulage engine is an old-type machine, previously driven by a single engine, and converted for its present use by the removal of the crank shaft and cylinder. The rope is steel, and is ¾in. in diameter. Two drifts are worked. One with a grade of 1 : 8 : the other about 1 : 12. They are both at present some 300 yards long, but will increase in length as the "face" recedes. The trams used are built entirely of iron. They average about 7cwt. empty, and carry about 22cwt. of coal ; so that each loaded tram represents a rolling load of about 29cwt. The wheels are 12in. in diameter, and each pair is keyed to the axle. The rails are of the girder type, and weigh about 28lb. per yard. The general condition of the road is well up to the average of colliery practice. The rolling friction, as measured by a dynamometer, on a level part of the road averages nearly 70lb. per ton. The drift with the 1 : 8 grade has two "partings" in continual use at present, and hence there is a great deal of shunting, stopping, and starting. The signals are given by a "rapper" and the motor is controlled by a lever similar to the regulator in ordinary use on steam engines. The notches correspond to different rates of motor power and speed. The trams can thus be moved a few inches at a time if necessary, and the speed can be varied from a foot per second to the desired maximum. An ammeter is placed in the circuit near the lever so that the brakesman can tell the number of trams on the rope and can also judge whether it is going right with the "journey." If, for instance, a tram leaves the metals, the ammeter needle registers more than the maximum current for the full load ; the driver at once stops the motor and brakes the drum. The tram is then set right, probably before any damage is done. The power absorbed by the drum and rope averages about 5 horse-power. The various horse-powers, speeds, strain on ropes, &c., corresponding to rolling loads of from one to six full trams, are given in the Table on following page, calculated from actual tests. The ohmic resistance of the cable is 1·25 ohms, and the energy lost for the different loads is shown in the Tables. The engine has not been indicated, and so the efficiencies can only be calculated between the outputs of the dynamo and the actual work on the rope. It will be seen that the electrical losses are small. The heaviest loss is that incurred by the friction of the drum and rope. This could probably be reduced by designing special gearing. Accepting things as they are, the efficiency between the maximum work on the rope and the probable indicated horse-power of engine is about 50 per cent. The strain on the rope on the 1 : 8 grade was measured by a dynamometer, and the result averaged for one and two tram readings. It is fairly represented by a pull of 4·5 cwt. per tram. Taking the grade as 1 : 8, the resistance due to gravity is 280lb. per ton. The average resistance measured by dynamometer on the

E.M.F. at dynamo	416	463	490	511	518	520
Horse-power lost in dynamo	·84	1·4	1·98	2·75	3·63	4·69
Estimated horse-power given out by dynamo	11·42	16·14	20·69	25·21	29·51	33·46
Horse-power given out by motor	9·97	13·74	17·24	20·57	23·28	25·43
Ratio between horse-power given out by motor and estimated horse-power given out by dynamo	87·5 per cent.	85·5 per cent.	83·5 per cent.	82 per cent.	79 per cent.	76·5 per cent.
Ratio between horse-power in rope and estimated horse-power in dynamo	43·2 per cent.	56·6 per cent.	63 per cent.	63·5 per cent.	64·5 per cent.	67 per cent.

level was 70lb. per ton. These figures show on inspection the high efficiency that a properly designed electrical plant is capable of. If we take the dynamo conversion at 85 per cent. and the engine efficiency at the same figure, the total efficiency for six trams (*i.e.*, the ratio between work in the rope and the indicated horse-power of engine) will be equal to 67 by ·85 by ·85=48·5 per cent. The motor is also arranged to run a set of three-throw pumps. When these are running, the hauling drum is thrown out of gear.

Andrew's House Pumping Plant.—As a good sample of dip pumping by electricity, I will refer to a small plant erected at Andrew's House Pit, for Messrs. Bowers and Partners. I am enabled to give these details by the courtesy of the manager, Mr. Berkley, junior. The plant comprises two sets of three-throw pumps, with suitable dynamo, &c., and is designed to cope with two small feeders, one about a mile in-bye, and the other rather more. The water was previously raised by two "cranks," each equipped by eight horses, working in pairs for three-hour shifts. The engine has a horizontal cylinder 12in. by 24in., and runs at about 38 revolutions per minute. The steam is controlled by a governor working on a throttle valve. The dynamo is shunt-wound, and gives about 270 volts and 18·5 amperes. The positive cable, about a mile long, is composed of a strand of seven No. 18 B.W.G. copper wires, insulated and lead covered; the *return* is made by an old iron rope about an inch in diameter, laid along the side of the road. The resistance of the entire cable is about 4·5 ohms. Both the motors are fitted with suitable starting and stopping gear, and are independent of each other, so that both or either pump can be run at pleasure. The delivery pipes are about 750 yards long. The quantity of water now being pumped by the two motors is about 60 gallons per minute. The lift from end to end is 44ft.; but owing to friction, &c., the effective resistance is equal to a head of certainly 60ft. The pumps are three-throw rams, 3in. by 7½in. The speed averages 60 revolutions per minute. The plant is a very small one, but is probably the most efficient that could be used under the given conditions. It is interesting, particularly on account of the distance through which the power is conveyed under ground. One motor has been running since Whitsuntide, the other a shorter time. The plant continues to give satisfaction.

Linlithgow Pumping Plant.—Another illustration of the application of electricity to transmitting energy through a long distance is a small pumping plant at the Linlithgow Shale Oil Works, Linlithgow. In this case one of the main engines at the Shale Mine Bank was used to drive a 4 to 5 horse-power dynamo, in addition to its regular work. The electricity thus generated was carried by a bare copper cable carried upon insulators on poles to an old quarry about one and a-quarter miles distant. The wire is No. 10 B.W.G., the current about 10 to 12 amperes, and the tension at the dynamo terminals some 300 volts. At the quarry a motor is geared to a double-acting pump, with a 2½in. bore and a 2ft. stroke. The water is raised through about 600 yards of 2in. pipe, with a vertical rise of 135ft., and is stored in a reservoir. The pumps at 40 revolutions per minute deliver about 33 gallons. The pump house is visited about once a day for lubricating and inspecting the machinery; no further attendance is required. The condition of the pumps and their rate of delivery can be told by simply inspecting the ammeter and voltmeter in the engine-room. The resistance of the cable, four thousand yards of No. 10 B.W.G., is about 7 ohms; and the loss in it averages about 1 horse-power. The main engine is not appreciably affected by the small load, and the cost of maintenance is practically nothing beyond the wear of the plant. By no other means could the same work be done so cheaply and easily. The plant has now been running for about nine months. Mr. Hamilton, the manager of the shale mine, is thoroughly satisfied with the work done, and reports a considerable saving over the estimated cost of the various alternative schemes proposed at the time of ordering the electric plant. These plants have been selected from amongst the most recent installations carried out by Messrs. Immisch and Co. They are typical of work obtained in mining, and show the means adapted to suit electrical plant to the everyday requirements of the coal pit.

THE SLATTERY ELECTRIC METER.

We illustrate this week, from the *Electrical Review* of New York, the Slattery meter, manufactured by the Fort Wayne Electric Company. The readings are direct, in lamp-hours or ampere-hours, as desired, and are said to be almost absolutely proportional throughout the whole range of the instrument.

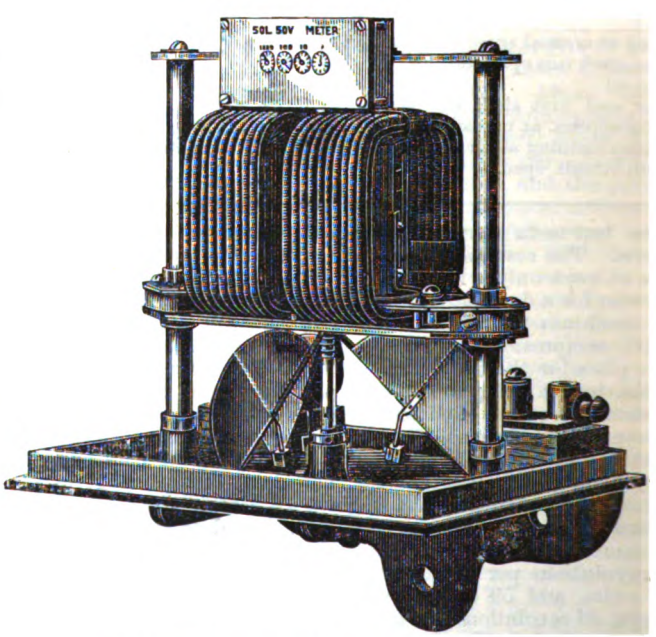

Fig 1.—The Slattery Alternate Current Meter.

The general principle of this motor-meter is the combination of two angularly disposed coils carrying primary and secondary alternating currents, with a movable portion or armature consisting of a very light cylinder of copper, the field of force resulting from the lag of phase as between the two coils. The small amount of inertia possessed by this cylinder permits it to start with a load as low as one 50-watt lamp. The secondary coil is naturally of low resistance, and one form is very quickly and conveniently made by nearly dividing a polygonal shell of copper by saw cuts into parallel sections, leaving, however, a mid-rib to support the sections. By this means coolness, and

Digitized by Google

the prevention of eddy currents, are obtained. The loss of energy in this meter is small. The sensitiveness of the meter may be increased by the addition to the copper cylinder of very light iron discs attached to its periphery in planes normal to the axis, though these are not essential.

An ingenious method is adopted to make the rotation proportional to the current. In electric motors in general the speed of rotation increases practically as the square of the current. For meter work retarding vanes are often adopted to reduce the speed for convenience of registering, but the atmospheric resistance of such vanes does not follow precisely the same law, since the retarding effect finally becomes proportional to a higher power than the square of the speed. In the Slattery meter, however, the vanes are constructed with jack-knife blades, which close on the vanes as the speed increases, thus reducing the exposed surface, and allowing the speed to increase to the proper extent. The relations are such that the rate of increase of speed exactly accords with that of the current, and great accuracy is thus attained.

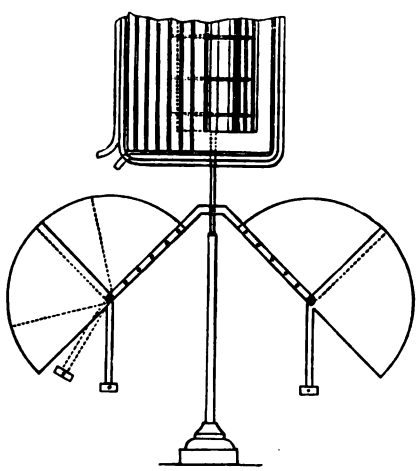

FIG. 2.—Slattery Meter—Outline of Vanes.

In Fig. 1 we have a general view of the complete meter, with its cover removed. In Fig. 2 we have a simple outline elevation showing the arrangement of the vanes for automatic adjustment of their exposed surface. As the speed rises the centrifugal force causes the pivoted outer blades to swing back and overlap the inner blades, thus reducing the surface.

THE LIGHTING OF THE CITY.

SPECIAL MEETING OF THE COMMISSIONERS OF SEWERS.

A special meeting of the Commission of Sewers was held at the Guildhall on Monday, to consider the question of electric lighting in the City, and to resume the debate on the report of the Streets Committee, which had in the meantime been printed and circulated. The report of the Streets Committee was briefly as follows:—Advertisements having been issued, tenders were received on May 10th last from the Anglo-American Brush Electric Light Corporation, for the west and central districts; the House-to-House Electric Light Supply Company, for the eastern district; the Metropolitan Electric Supply Company, for the western district; the Laing, Wharton and Down Construction Syndicate, east district; the London Electric Supply Corporation, all three districts. The Commissioners have since received notices from the Anglo-American Brush Electric Light Corporation, Metropolitan Electric Supply Company, London Electric Supply Corporation, the Laing, Wharton and Down Construction Syndicate, that they will in the next Session apply for Provisional Orders to supply electricity within the City of London. On carefully considering the tenders sent in, together with the suggestions of the companies in regard to conditions, it was found that the tender of the Anglo-American Brush Corporation was the only one practically in accordance with the specification, and under the advice of Mr. Preece, we instructed the officers to negotiate further with the Metropolitan Electric Supply Company and the London Electric Supply Corporation with a view to arrange similar terms with them. This has since been done, with the result that they have severally modified the terms of their tenders, so as to bring them into uniformity with that of the Anglo-American Brush Corporation, and broadly, all these three companies now agree to accept the terms of the original specification, modified only in terms of the Provisional Orders now sanctioned by the House of Commons. The prices per annum per arc lamp are as follows:—London Electric Supply Corporation, £24. 3s. 10d.; Metropolitan Electric Supply Company, £26; Anglo-American Brush Corporation, £26. The first-named company having agreed to waive the condition as to extinguishing half the lamps at midnight, say the price is to be £26 per lamp. After full consideration, we beg to recommend that the tenders of the said three companies be provisionally accepted, subject to their agreeing to enter into a contract for 21 years, determinable by either party at the end seven or 14 years. All the companies agree to make the contract for public lighting determinable at the end of seven, 14, or 21 years. That the three districts into which the City is divided for this purpose be allotted as follows, viz.:—No. 1, West, to the Metropolitan Electric Supply Company. No. 2, Central, to the Anglo-American Brush Company. No. 3, East, to the London Electric Supply Corporation. To light the main thoroughfares by means of 395 arc lamps will cost £10,024, in place of 1,730 gas lamps, now costing £5,530 per annum, but whilst the price will not be double that of gas, the amount of light will be many times greater.

At the suggestion of the CHAIRMAN, the discussion was taken *de novo*, and the Chairman formally moved the adoption of the report.

Mr. SLY, referring to the paragraph of the report in which the amount of electric light is spoken of as being many times greater than that of gas, said this was cleverly, if not artfully, drawn. The word "many" might mean ten times or five times greater. They ought to know what the difference would be. If it was six times, or even three times the amount of light, they did not want it. It was a grave question whether they wanted twice the amount of light in the City. Might they not have 500 candle-power at something like half price? The cost of lighting the whole City at the present time was £11,000, and if they doubled that it would be £22,000. They ought to have been told fully what this interesting experiment was going to cost. He presumed there would be some expense connected with pulling up the streets which had not been allowed for. They might have to go to arbitration, which would involve further expense. He did not think there had been a strongly-expressed desire for electric light in the City, and he submitted that they were not behind other places.

Mr. PANNELL deprecated at this particular time discussing the whole question of electric lighting over again. He took it that the Commission had virtually decided the general question, and what they had before them was the report of the Committee. He was going to move that the report be referred back for reconsideration, which was what the Committee really required. The Committee wished to take the Commission into their confidence at this point, and submitted details as far as they had gone. The Anglo-American Brush Corporation had come on to a common platform with the Commission some time ago, but the other two companies had not come to the same agreement for tendering. There was a requisition for certain information which two of the companies did not give. The Committee said:—"The contractor must give a complete description of the lamps proposed to be used, of the power in watts they consume, and of the light in candles they emit, both of the arc and the glow lamps. The lamps must be so placed that the light distributed over the public ways shall be as uniform as possible, and those tendering will have to demonstrate upon a plan and section, which is to be sent in with the tender, the relative intensity of this distribution of the electric and gas light. The standard of reference will be the illumination of a square foot of surface by a standard candle at 12·7 inches distance." The London Electric Supply Corporation gave certain information, and then said the lamps should be "of the description most suitable to their respective purposes, and the best procurable at the time of installation." That was sufficiently vague. He did not think they could deal with a company that made such an indefinite reply. The Anglo-American Brush Company gave the date when they would commence to light the thoroughfares as required by the Commission; but the London Electric Supply Corporation said "as soon as possible after statutory powers are granted." This company also would only undertake to keep in repair such standards as were erected by them. They would be prepared to utilise such existing standards as might be suitable for their purpose, but they would not be inclined to repair, paint, and maintain them. As regarded price, whilst the other companies stated their price plainly, the London Electric Supply referred to the Provisional Order. This company at the expiration of seven years could give notice to terminate the contract as regarded public lighting and continue to have facilities for private lighting in the district. The Metropolitan Supply Company would charge 6s. 8d. per unit, which was equivalent to 8d. per Board of Trade unit. This was for private

Digitized by Google

lighting, but the price for the public lighting would be 3d. a unit. Supposing the company said at the end of seven years, "We are not going to continue the public lighting at 3d.; we will give notice to determine that contract, but we shall have power to continue the private lighting at 8d." Mr. Pannell proceeded to show that the London Electric Supply Corporation gave unsatisfactory answers to other questions. It was just possible they might accept the terms agreed to by the other companies. His object was not in any way to delay the question of electric lighting, but rather to speed it.

Mr. C. T. HARRIS contended that the Committee recommended the Commission to accept tenders on totally different lines from those agreed to by the Commission. The sliding scale was swept away altogether. No arrangement was made for the payment for gas by the contractors during failures, which was always an important item. None of the three schemes agreed, but they were entirely different. He thought they ought at least to have something like uniformity. He was not quite certain that the Brush Company was in a condition to undertake work of a large character like this. He greatly objected to the mode of lighting. To replace 1,730 lights by 395 was a policy of suicide. The Committee had not said how many times greater would be the light, because they could not. It was never the same two seconds together. Mr. Preece had consistently told them that the arc light was not suited for street purposes, and their engineer had always consistently and persistently told them that they must not diminish the number of lights in the City. They wanted diffusion instead of extreme concentration. He reckoned, with all the necessary additions, the cost would be about £13,000, and they would get a much better lighting if they would only turn their attention to improved gas burners.

Mr. INNES said it was with deep regret that he came to the conclusion, as a man of business, that the report must go back. He desired to have electric light on as reasonable terms as possible. It was perfectly obvious they could not accept the terms of the London Electric Supply Company.

Mr. Deputy BEDFORD said if they were going to wait for all possible improvements they would have to wait a long time. He was in favour of having what they could get now. The matter had been referred to their engineer and one of their ablest electricians, Mr. Preece, and they said, "Adopt this report." Let them take a good step forward.

Mr. Alderman MOORE was deeply disappointed that they could not accept the report. He thought the Commission would be very nearly justified in accepting the Anglo-American Brush Company's tender, and their object in sending the report back was to bring the terms of the other companies into conformity with that. They ought to have a larger number of arc lamps so as to have a much better diffusion of light. With these modifications, he thought they might pass the Brush Company's tender at the next Court.

Mr. SHAW thought they ought to have had a much simpler report presented in terms as short as possible. He wished to give the electric lighting companies as much encouragement as possible to carry out the work, but they must carefully consider the conditions under which they are to act. If there was a possibility of getting this light at anything like the price of gas, they ought to have further inquiry. It was only within the last two or three weeks that a new economical system was brought to his notice; a system which could be worked without a dynamo. They wanted to have not only a success, but an economical success.

Mr. DAY (Chairman of the Streets Committee) in replying to questions, said the amount of the electric light would be from four to six times that of gas. It was not quite clear what the Commission wished the Committee to do in sending back the report. Various objections had been raised, but they had not been put in a concrete form.

The amendment was carried by a large majority, and the report was referred back.

The Commission then adjourned.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 12, 1889.

A very important decision, of which you probably have already heard by cable (*Electrician*, October 18th), has just been rendered in the electric light field. It is early yet to determine just exactly its scope and effect, but there is no reason to doubt that it will have a material influence on the future of the incandescent lamp. The case is that of the Consolidated Electric Light Company against the McKeesport, Pa., local Edison Company, for infringement, and is practically one between the Westinghouse and Edison interests, since the Sawyer-Man patent involved is now owned by the Westinghouse Company, while the Edison parent Company has naturally taken up this suit in protection of its local representative. The suit was brought on the patent granted in 1885, after considerable controversy and delay in the Patent Office, for a fibrous filament lamp, the main claim of the patent being for "An incandescing conductor for an electric lamp of carbonised fibrous or textile material, and of an arch or horse-shoe shape." The case was heard before Judge Bradley, of the United States Supreme Court, in the United States Circuit Court for the Western District of Pennsylvania, at Pittsburgh. Judge Bradley, in his decision, goes very thoroughly into the points at issue, and after narrowing the patentable features down to the conductor of carbon made of fibrous or textile material, he has declared that such a patent is invalid. He holds, again, that there was no patentability in combining such a conductor with a glass chamber, nor in giving the conductor an arched shape. These features were old in the art, and furnished no good ground for a patent. Coming to the question whether the patent could be sustained on the fibrous filament conductor itself, Judge Bradley declares that this again is nothing new. Long prior to 1878, he says, it was a well-known fact in science and the arts that the transmission of the electrical current through a pencil of charcoal interposed in a metallic circuit would produce intense light, and that when this charcoal was guarded from the air by being placed in vacuum it could not be consumed. "We are clearly of opinion," he says, "that neither Sawyer and Man nor Edison can maintain any just claim to the exclusive use of charcoal generally in any form as an incandescing conductor in an electric lamp." This view of the case would be sufficient in itself to invalidate the patent, but Judge Bradley dives into the evidence, and brings forward data from it to show that in their original application Sawyer and Man had no such idea in view as that of claiming broadly all carbon made from fibrous or textile material as a conductor in incandescent lamps. Their original intention, he says, as clearly revealed by the evidence, was to secure a patent on the carbon arch. Finding that this was untenable, the original application was from time to time amended so as to embody the fibrous carbon filament matter as a broad principle. Judge Bradley says, however, that he is not at all satisfied that Sawyer and Man ever made and reduced to practical application any such invention as is set forth and claimed in the patent in suit. In fact, said Judge Bradley, Sawyer and Man were following the wrong principle, as many another had done before them, and seeking to secure the practical commercial incandescent lamp by adopting a filament of small resistance with a strong current, whereas the great discovery in the art was that of adopting high resistance in the conductor with a small illuminating surface and a corresponding diminution in the strength of the current required. "This was accomplished by Edison in his filamental thread-like conductors, rendered practicable by the perfection of the vacuum in the globe of the lamp." Judge Bradley then goes on to quote largely from Mr. Edison's patents, showing the evolution in them of this idea of the filament of high resistance, and says, after doing so, "We think we are not mistaken in saying that but for this discovery electric lighting would never have become a fact. We have supposed it to be the discovery of Edison, because he had a patent for it. This may not be the case; it may be the discovery of some other person. But whoever discovered it, it is undoubtedly the great discovery in the art of practical lighting by electricity." This is practically the gist of this decision, which runs a length of from eight to ten thousand words, and which invalidates the patent upon which, had they been successful in sustaining it, the Westinghouse Company could have maintained a monopoly of all fibrous filament lamps It will be seen that the controversy in its legal aspects, even should this decision be appealed, as it may be, narrows itself down to the validity of lamps of high resistance, in regard to which the work of Mr. Edison seems likely to withstand well nigh every attack. The Edison people, therefore, although Judge Bradley denies to them, equally with Sawyer and Man, the peculiar right to the fibrous filament, are inclined to look upon this decision as so much in their favour as to give them the monopoly which the Westinghouse Company proposed to

Digitized by Google

secure for itself. Time and further litigation alone can show how this will be, and it is of course to be borne in mind that Mr. Edison's patents so far are liable to forfeiture by the interpretations which have been made of the statutes referring to the expiration of the United States patents on account of the expiration of similar foreign patents. It is urged that Mr. Edison would not have been so anxious to upset the decision against him in Canada unless he had felt his interests in the United States to be imperilled by them. Still, as matters stand at the present moment, the position of the Edison Company is appreciably stronger than it was, and no doubt the most will be made of it. It is somewhat of an odd coincidence worthy of note that Judge Bradley's decision, strongly against the Sawyer-Man's claims, came the same week as Mr. F. L. Pope's interesting book was published on the evolution of the incandescent lamp, attributing to Sawyer and Man the glory and the merit of doing just what we are now told by that high authority they did not do. I do not suppose that Mr. Pope will call in his book, but had he known what was coming he probably would have published it before, or never at all.

As might be expected, the Westinghouse and Edison people have been exchanging compliments over the situation, and these furnish amusing, if not instructive, reading to the public. Mr. Westinghouse claims that the business and profits of his company will not be affected materially by this decision, but that, on the contrary, if the impression gets abroad that the incandescent lamp has become public property, the demands for electric lighting will be increased, and his company will come in for its share. Mr. Edison, who returned from Europe the very day after the decision in his favour had been rendered, was naturally well pleased at it, but could not refrain from saying that Mr. George Westinghouse was once a pretty good sort of a fellow, but had stolen some fifty of his patents, and degenerated into a mere "shyster." There is some curiosity in electrical circles to know just how the Thomson Houston Company, which manufactures its incandescent lamps under the Sawyer-Man license, will act in the circumstances, and just what effect it will have on the business in general. During the past few months there has been talk from time to time of a closer *rapprochement* between these various companies, but it would hardly seem likely, for the present at least, that any drawing together on terms of amity can well take place.

As your readers are perhaps already aware, a decision in the Kemmler case, involving the constitutionality of the New York State law providing for electrical executions (*Electrician*, October 11th), has at last been handed down. The decision is that of one of the county judges, but is none the less important for that. County Judge Day, on the habeas corpus proceeding to test the constitutionality of the law, decides that the law is constitutional, and he has remanded the prisoner to the custody of the warden of Auburn prison for the execution of the sentence. Besides dealing with the constitutional points involved, which are not likely to be of interest to the electrical reader, Judge Day asks whether in this case it has been plainly and beyond doubt established that electricity as a death dealing agent is likely to prove less quick and sure or more painful than the rope. He answers his own question in the negative, and says that before the statute can rightly be abrogated there should be positive judicial knowledge that the punishment provided is actually cruel and unusual. There is no such knowledge, Judge Day holds, and, therefore, the contention of Kemmler's counsel fails. Mr. Bourke Cockran, the counsel in question, says that he expected such a decision, it being hardly likely that a county judge would take upon himself the responsibility of upsetting the law. Mr. Cockran, therefore, will now appeal to the General Term and to the Court of Appeals.

The International Marine Conference, which begins at Washington next week, on the 16th inst., is one in which England is greatly interested. This conference will include representatives from all the great nations and maritime powers with the exception of Portugal. The gentlemen representing Great Britain are Mr. C. Hall, M.P.; Mr. Thomas Grey, Secretary of the Board of Trade; Captain Wyatt, of the Peninsular and Oriental Steamship Company; Captain Kendall, of the Dublin Steamship Company; and Admirals Molyneux, Smith and Nares. Some thirteen main subjects of discussion will be brought before this body, and several of them are of interest to electricians, especially those which deal with lights and signals afloat, and with lighthouses and the patroling of seaboards. Such a Conference will, undoubtedly, do much to simplify and render uniform the lights and signals of the different nations, and in so doing may be expected to favour and recommend for general adoption the various electrical devices that have been found practicable and successful in the different navies and large steamship lines. It is interesting to note, for example, that two vessels of our navy—the "York Town" and the "Dispatch"—have for some time past been experimenting at Newport on running lights and sound signals, and that a report will be presented for the consideration of the Conference. Apart from the question of lights and sounds, there is great interest attaching to the question of saving life and property from shipwreck, and I should not be surprised if attention is drawn to the results obtained in England in connecting light-ships with the mainland for telegraphic and telephonic purposes.

CORRESPONDENCE.

THE PRACTICAL UNIT OF INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Glazebrook ends his letter in your issue of last week, "Prof. Ayrton graduates his voltmeters in legal volts. Let me ask him to graduate his new standards of electromagnetic induction in 'legal quadrants.'"

May I ask what is a "legal quadrant?" I understand what a B. A. quadrant (query "illegal" quadrant) is, viz., 10^9 C.-G.-S. units of induction. But what is this "legal quadrant?" Is it a secohm? If so, why not call it a secohm, seeing that some thousands of coefficients of induction have already been measured in secohms, and that the name "secohm" is short and correct, while the name "legal quadrant" would be as wrong as it is long? To call a secohm a "legal quadrant" would, in fact, remind one of the schoolboy's definition of a crab—a red fish that walks backwards—for a secohm is not a quadrant, and, like the commercial ohm, has nothing legal about it. I do not know whether Mr. Glazebrook is aware that in communications to Government departments the expression "legal ohm" has been found not permissible, as the eye of the law has as yet taken no cognisance of that unit. And just as, in spite of my great admiration for the splendid work done in the past by the B. A. Electrical Standards Committee, I have always thought they made a mistake in calling their system of relative ideal units "absolute," so I venture to think that the Committee are now making a similar mistake in calling their commercial system of units "legal."

But perhaps, as the Paris Electrical Congress have stated in their resolution that a secohm is 10^9 C.-G.-S. units of induction, which it certainly is not, it is possible that Mr. Glazebrook's "legal quadrant" is not a secohm. If so, will he kindly give us an *exact* definition of a "legal quadrant," not, of course, in terms of a second and a commercial ohm, for, according to Mr. Glazebrook's view, "the coefficient of induction is necessarily the more fundamental quantity of the two." His statement that the "legal unit of electro-magnetic measure is somewhere about $\cdot 99777 \times 10^9$ centimetres," is, of course, not intended to be a definition any more than the statement that an English yard was somewhere about a certain fraction of a metre would be a definition of a yard.

If the name "effective current" is to be given to the square root of the mean square of a current, I should like to ask, while on the subject of nomenclature, what the square root of the mean square of a current is to be called when it is *not* the effective current, as in the case of an alternate-current permanent magnet motor?—Yours, &c., W. E. AYRTON.

THE PRACTICAL UNIT OF SELF-INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue two letters appear discussing reasons for and against the exchange of the names secohm and quadrant. The word *secohm* seems to me much to be preferred, be-

Digitized by Google

cause it is simpler and more expressive. The unit of self-induction depends on the *second* and the *ohm* in exactly the same way as the *foot-pound*; the unit of work depends on the *foot* and the *pound*. In fact, most of the methods of measuring self-induction give it directly as the product of a time and a resistance. The name secohm was a suggestion from this college, where a very large number of induction measurements have been made, and it had already come into general use.

Mr. Glazebrook says that it was felt "desirable to emphasise the fact that the self-induction of a coil in electro-magnetic measure was a quantity which could be determined with a metre scale, or something equivalent to such a scale." This is only true, however, in a specified medium. If the coil is taken into another atmosphere its self-induction is changed, although its size is unchanged. The self-induction, if measured in *quadrants*, would be unaltered, but if experimentally determined in *secohms* would be found to be changed. The latter unit must, therefore, be the true one, for everyone knows that the self-induction of a coil is increased if iron is brought near it.

Prof. Rücker has pointed out that the dimensions of permeability and specific inductive capacity have been suppressed simply because they are unknown. The electro-magnetic and electrostatic units appear in consequence to differ in dimensions, although a unit of electricity must necessarily be the same kind of quantity, however it is measured. This inconsistency causes a great deal of quite unnecessary difficulty to students, and I think it tends to retard the progress of Maxwell's theory of electricity by making it appear unintelligible.—Yours, &c.,

Central Institution, October 24, 1889. W. E. Sumpner.

THE PATTEN ALTERNATING-CURRENT MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The Paper by Lieutenant Patten, published in your issue of the 11th inst., reminds me of an experiment I made many years ago, about 1880, with two alternate-current Wilde machines, at Latimer Clark, Muirhead and Co.'s Works. It will be remembered that these machines are magnetised with the current from two of the armature bobbins, which is connected into a continuous current. By passing the alternate current of the one machine into the armature of the other machine by the two ring collectors, and connecting the commutator brushes of the magnetising coils parallel to the collecting rings with a resistance in circuit, the machine ran as a motor. I took some measurements, but I cannot find the data now.

It is not easy to see how the synchronism of Lieutenant Patten's machine is maintained; a perfect balance between the winding of the machine and number of alternations is difficult to conceive.—Yours, &c., J. D. F. Andrews.

Glasgow, October 21, 1889.

ACCUMULATORS AT THE PARIS EXHIBITION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your last issue under the heading "Accumulators at the Paris Exhibition" you gave a list of awards which is incomplete and misleading. Will you allow me to correct it thus: Gold Medal to M. Faure and to l'Electrique de Bruxelles, working under the Faure and Julien patents. The Electrical Power Storage Company, of London, for its system of electrical distribution (King's patents) and the Société Française des Accumulateurs working also under the Faure and other patents, obtained Silver Medals. The Electrical Accumulator Company, of New York, did not exhibit individually, but derives benefit from the award to Faure.—Yours, &c., C. A. Faure.

19, Avenue de Villiers, Paris, October 19th, 1889.

THE SILVERTOWN STRIKE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As reports are still being circulated that we underpay our workpeople, we should be glad, with your permission, to re-state their average weekly wages and hours, viz.:—

Labourers	26s. 3d.	for 63	hours.
India-rubber departments	33s. 7d.	„ 63½	„
Cable and Telegraph departments	28s. 1d.	„ 60	„

for permanent work in healthy buildings.

We also employed about 350 women and girls, who, on an average, earned 13s. 5d. for a week of 54 hours.

These wages are higher than those paid by any other firm in our trade, and the directors have decided not to pay more.

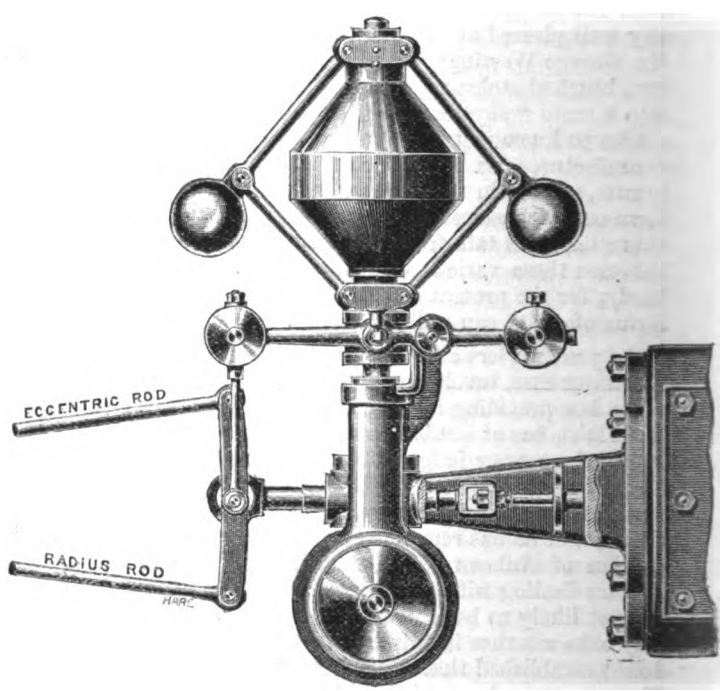
Hitherto the company have not engaged, or tried to engage, new hands, though a considerable number have applied for employment. The pickets who surround the factory are therefore employed in keeping out, not new men, but our former workpeople, who, so far as we are concerned, are free to return so soon as we can arrange work for them. To describe the stoppage of our works as a lock-out is therefore untruthful. It is the strike leaders who are responsible for the increasing distress in Silvertown and its neighbourhood.

The directors have been asked for an interview by a few of our workpeople, and by agitators who have never been in our employment and have made themselves conspicuous for misstatement and abusive language. Of course, the directors cannot consent to such an interview.—Yours, &c.,

October 17, 1889. Wm. J. Tyler, Secretary.

AUTOMATIC EXPANSION GEAR FOR ELECTRIC LIGHT ENGINES.

We illustrate below an improved form of automatic expansion gear made by Messrs. Ransomes, Sims and Jefferies, of Ipswich, and which is specially adapted for engines employed in connection with electric light machinery.



In this apparatus an independent gridiron expansion valve, working upon the back of the main slide valve, is operated through a knuckle joint by a link, one end of which is actuated by the cut-off eccentric, while the other end is held by a radius rod. The travel of the valve and the point at which it cuts off are governed by the position of the link in relation to the knuckle joint, and this position is varied in accordance with the load on the engine by a powerful and sensitive governor to which the link is connected. By this arrangement the cut-off can be varied between 0 and 70 per cent. of the stroke in proportion to the actual load for the time being on the engine, and the exact amount of steam necessary to do the work required being admitted at full boiler pressure up to the point of the cut-off, the entire benefit of the principle of expansion is obtained, and, in cases where an engine is required to work under varying loads, a very considerable saving in the fuel consumed is effected. In addition to the advantage arising from the economy effected in the fuel consumption by the adoption of this gear, the speed of the engine is maintained practically constant under very great differences of load, the variation in the number of revolutions in no case exceeding about 2 per cent.

COMPANIES' MEETINGS & REPORTS.

The Eastern Extension, Australasia and China Telegraph Company (Limited).

The thirty-second ordinary general meeting of this Company was held on Wednesday, at Winchester House, 50, Old Broad-street, London, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. F. E. Hesse) read the notice calling the meeting, and the minutes of the thirty-first ordinary general meeting, which were confirmed by the present meeting and signed as correct by the Chairman.

The report of the Directors was taken as read.

The CHAIRMAN: Before I ask you to approve of the report, I shall as usual make a few remarks upon the working of our system during the last six months. The gross receipts for the half-year amounted to £256,757, against £239,926 for the corresponding period of 1888, showing an increase of £16,831, which is due to general growth of business all over the system. The working expenses have been £73,773, against £69,297 for the corresponding half-year, showing an increase of £4,476. This increase is principally caused by the opening of the Company's station at Roebuck Bay, in connection with the Western Australian cable, and the construction of a new pipe land-line between the cable house and office at Madras, about 1¼ miles long, costing £1,364, to replace the old one, which had been down for 10 years, and had become almost worn out. The net revenue has amounted to £138,736, against £125,804 for the corresponding period of 1888, showing an increase of £12,932. Interim dividends at the rate of 5 per cent. per annum have been paid for the half-year, leaving £26,236 to be carried forward, after debiting revenue with £50,000 on account of the Western Australian cable. It will be in your recollection that when we had our two cables interrupted to Australia through volcanic action, we decided, without any delay whatever, to put down an additional cable to Australia, so as to give us security and continuity in our connection with our Colonies. That cost a large sum of money, but it did not bring us in any additional traffic. It was practically a reserve, and since the cable was laid we have had good reason to congratulate ourselves on having laid it at the time we did, because there have been interruptions on the land lines of Australia, which would have very seriously interrupted the traffic if this cable had not been laid. Consequently, it maintains our revenue, and we have thought it would be a wise thing to pay for the cable as quickly as possible out of revenue. It has always been our policy, as you are well aware, to keep down capital as much as possible, and therefore we have taken a very broad view of this matter, and have written off at one sweep £50,000 on account of the cost of that cable. We are, however, still enabled to maintain our dividend as heretofore and to carry forward a very considerable sum to next half-year. As to the balance of the cost of the West Australian cable, we shall in dealing with it be determined to a large extent by the progress and prosperity of our system during the next six months. I think I mentioned when I addressed you six months ago that we were gradually carrying out our system of renewals in maintaining our cables. I see that in the last six months we renewed about 132 knots of cable, at a cost of something like £8,000. Since the 30th June we have renewed about a similar quantity, and with the further work we are now engaged upon we shall nearly complete the renewals that we have in view at the present moment. We are thus strengthening our system by these renewals, and are able to maintain a thoroughly efficient service. Taking the matter altogether, I hope you will approve the policy which I have just indicated, and which I think has worked on the whole very satisfactorily. We have also since this half-year began had an important interruption in our New Zealand cable—an interruption that extended over twelve days, and which so seriously interfered with the traffic between New Zealand and Australia that we determined without any delay to lay down a duplicate cable. We considered that, as the traffic with New Zealand was increasing, and the cable had been down for fourteen years, the sooner we duplicated it the better. We have, therefore, communicated with the New Zealand and New South Wales Governments, proposing duplication on certain terms, and not a minute too soon, because by the last advices we had from New Zealand we found that in that Colony the people were appealing to the Government for a duplicate line. Well, gentlemen, I am not sorry that they should have felt some inconvenience after their treatment of us a few years ago, when we were fighting with the New Zealand Government for our rights, which I think we practically gained. We have not yet received replies from the Governments interested, but I am hopeful that before a week passes over our heads we may be in a position to go on with the duplication of the New Zealand system. I think it is well that you should understand that duplication is a policy which we have found to work well. We have found it desirable to be ahead of our work, so to speak, and although this duplicated cable will not bring us any additional income, it will secure to us the income that we are already earning, and which I am glad to say is growing. I am pleased to tell you to-day that all our cables are in good working order. When I tell you that we have got something like 14,000 miles of cable at the bottom of the sea you will understand that it is a very great thing to be able to say that they are all working well at the present moment. I may also, in speaking of the New Zealand duplication, make a few other remarks in passing, because I think it is our business to give our shareholders as clear a view of our policy as possible. You have heard a great deal about a Pacific cable—an opposition line—the object of which is more to reduce our rates than to give increased facilities. Our present line is equal to a great deal more work than it at present transmits, but if the Governments of our Colonies or our own Government determine, for strategical purposes, that a Pacific line should be laid, we are quite prepared to undertake it. Not that it would bring any additional commercial traffic to us; but we feel that our system is so important, both commercially and politically, that it would be our duty to lay this line if we are fairly and properly remunerated. The line to New Zealand which we propose to duplicate would be what you may call the first link in the Pacific system, of which Fiji and the other islands lately acquired would form points of departure. Other work is very likely to be done in connection with our system. The French have New Caledonia, and I believe that must eventually have telegraphic communication. Therefore, while I may say that we have a consolidated position, we also occupy to some extent a restless position. We can never sit down quietly. We must meet every requirement as it comes up and maintain the position of invulnerability which I believe we now maintain. We have also negotiations with Spain going on at the present time for connecting the Philippine Islands. British North Borneo is growing and will require a telegraph by-and-bye; and altogether we have plenty of work before us, and it will be our duty to meet such requirements, always having due regard to the interests of our shareholders. At the last meeting I referred to our Six per Cent. Debentures, and remarked that 6 per cent. was a high rate of interest, and that I should be very glad to see them wiped out. But, unfortunately, those who hold the debentures know their value, and it is very difficult to get them out of the way. Though this is not the time to deal with them, we have the matter in view, and when they expire, which will be in 1891, we shall deal with them in a way that will, we hope, be perfectly satisfactory to our shareholders. We have a large number of debentures guaranteed by the Australian Government subsidies which are all being provided for, and by the time the subsidies expire those debentures will be extinguished. Therefore, I may congratulate you on the sound position which we occupy. I can also congratulate you on the friendly relations that exist between your Company, the Colonies, and in fact all those whom we serve, and I congratulate you again to-day on our being able to present to you a satisfactory dividend, and six months hence I hope we shall be in a position to add a handsome bonus to the dividend. I now move—

"*That the report and accounts of the Directors now submitted be received and adopted.*"

Mr. FRANCIS AUGUSTUS BEVAN seconded the motion.

The CHAIRMAN: If any gentleman wishes to put any questions to me I will endeavour to answer them to the best of my ability.

Mr. LEWIS said he saw that they had an account of investments of their reserve fund—nearly £700,000—yielding only 3 and 4 per cent., while, on the other hand, they had debentures to the extent of £320,000 on which they were paying 6 per cent. He thought if it were the case of any private man of business his first object would be to pay off that £320,000. Considering the price of money lately, he thought that the Six per Cent. Debenture holders had had a very fine time of it, but it was time that that rate of interest should cease. The Directors had taken £50,000, which was rather a large amount, out of the earnings towards paying off the debt on the Western Australian cable, leaving a balance for the half-year of £26,000 to be carried forward. Considering the dividend they were getting, he thought the Directors might have been content to spread the repayment of £50,000 over a little longer time; but, not content with that, they swept away again as much as the £26,000 they carried forward, making altogether a sum of £76,000 taken out of revenue. The revenue for many years had been constantly increasing, but the shareholders never seemed to get any more dividend. In 1880, and for five years afterwards, in each October they received 1s. 6d., and sometimes as much as 2s. added on, but since 1885 they had had the stereotyped 2s. 6d. It seemed to him that instead of the shareholders profiting it was their banker, who had £107,000 in hand, while the traffic and other debit balances amounted to another £80,000. That being so, the Directors could surely have employed another £12,000 in giving the shareholders an extra 1s. Besides the amounts mentioned they had bills receivable to the extent of £41,000. He really thought, therefore, that the Directors might have given another 1s. or 1s. 6d., and kept up the return which they had for so many years, but which always was knocked off. It seemed to him that people who were shareholders now, and who had been shareholders in the past, were building up a very fine business for those who were to come afterwards. He thought that a very heavy sum had been spent on the maintenance of the ships, seeing that they had not had very much steaming to do. He had not made these remarks in any spirit of opposition.

The CHAIRMAN: I confess that I like a little opposition, and the gentleman who has just addressed the meeting has spoken with a very fair amount of reason. We are a very prosperous Company, I admit, and, as I hinted to you, we have done a very big thing in wiping off that £50,000 on account of the Western Australian cable. But we are a Company in a position to be shot at, and we have so to protect ourselves in every way that, while maintaining a good and respectable dividend, we are adding very materially to the value of your property. The price of your shares shows it. You cannot have your cake and eat it too. If you get your shares increased in value by the policy we are pursuing, I think it may be said that we are doing much better for you than if we put the money into your pockets, when probably you would spend it. But you have not been strictly accurate in your remarks as to the bonus. We pay a bonus once a year. Last year we paid a bonus of 3s., and there is no reason, as far as I can see from the working of the concern, why next time you should not receive as good a bonus as last time. But we only pay it at the end of the year.

Mr. LEWIS remarked that they used to have the bonus in October as well.

The CHAIRMAN: Yes; but it was agreed after the Berlin Conference, when we had to reduce our tariffs to the extent of something like £40,000 a year, that we should pay the bonus once a year, and pay a steady 5 per cent. dividend and any additional amount that might be distributed in the form of bonus, which might, of course, fluctuate. This is only the interim half-year, and next six months, if we do not pay you a bonus, I think you will have good reason to speak hardly of myself and co-Directors.

Digitized by Google

I may mention that we are approaching another Conference. These Conferences take place every five years. We were forced to come down very considerably in our tariffs at the last Conference, and I think at the present moment it is wise policy until we see what is going to be done at the next Conference to husband our resources. I admit that there would have been no difficulty in paying you 1 per cent. extra dividend. But I think it is very much better, and I believe I shall find that that is the view held in this room generally, to consolidate and add to the value of your property, complete your renewals, and do that which is necessary to maintain your sound 5, 6, or 7 per cent., as it may be. I think that is a better policy than having a dividend which keeps jumping up and down—a policy under which you get 5 per cent. at one time and 7 per cent. at another. We are strengthening our position, and we are securing you a permanent dividend. I may add one other remark, owing to what I heard the other day when I was coming from my place in the country. A gentleman said to me, "I always look almost to the day for your dividend. It always comes, and is always a respectable, good dividend. We trust to it for paying certain things." Now it is a very nice thing for investors to give you their confidence in that way, and I want to make the thing so certain that that sort of confidence will grow in the minds of investors. I do not wish to play into the hands of the Stock Exchange, but into the hands of sound and substantial investors—people who put their money into the Company to get a living by it. That is our policy; so far that policy has been pursued, and I believe you will admit that it is the soundest policy. As to the Six per Cent. Debentures, I think I gave you this hint—that they were too good for people to part with them; but if you will bring them all in to-morrow at a reasonable price we would at once take them.

Mr. LEWIS observed that it had been a very bad policy on the part of the Directors to specify no time at which the debentures were to be paid off.

The CHAIRMAN: But there is a time specified—1891.

Mr. LEWIS said he accepted the Chairman's statement, adding that he thought the debentures were hanging about the neck of the Company for ever.

The CHAIRMAN: You can have no better evidence of the progress of this Company than is afforded by these debentures. When we issued them we had a great deal of difficulty in obtaining the money. We have brought about confidence in the mind of the general public, and they are now pleased to have our debentures at 4 per cent. instead of 6 per cent. We have grown up step by step, and I think it is one of the most remarkable things done by these submarine telegraph companies that they have placed their debentures at about as low a level as is done in the case of any respectable undertaking in the city of London.

Mr. BLUNDELL presumed that the debentures would be paid off at par in two years, and that they would be absolutely extinguished then.

The CHAIRMAN: Do not ask me that. All I tell you is that these debentures will not be renewed at 6 per cent. He then put the motion in the usual way, and having declared it carried unanimously, said: That finishes the business of the day.

Mr. JOHN NEWTON proposed a vote of thanks to the Chairman and Directors for the manner in which they had conducted the business of the Company. In the early days of the Company some persons said that he (the speaker) was an adverse critic, but he did not think that he was. He agreed with Mr. Lewis making remarks, for it was advisable that there should be opposition before meetings when it was conducted in a friendly spirit. What had been said at that meeting had only confirmed him in the view he had maintained as to the debentures, but he was so satisfied at the way in which the business had been conducted that he would leave it in the hands of the Directors, especially in view of the abominable Telegraph Conferences, which always endeavoured to reduce the dividend paid by the Cable Companies. While there were Conferences, it was absolutely necessary that the shareholders should place implicit confidence in the Board, who had to deal with matters which could not be discussed at public meetings. As to the dividend which they were receiving, it ought to be remembered that 5 per cent. was as good as 7 per cent. eight or ten years ago. He was perfectly satisfied with what they received, and he had great pleasure in proposing that vote of thanks.

Mr. LEWIS, in seconding the motion, said he held Sir John Pender in such high esteem that he had recently taken some shares in a company because his name appeared as a member of the Board.

The motion was carried unanimously.

The CHAIRMAN: I am very much obliged to you, Mr. Newton, for the way in which you have proposed this vote of thanks to myself and the Directors. You have been watching these submarine cable companies from their very inception, and no man knows better than you their working and the care with which they have been conducted. A very great change has taken place in the value of money since these companies were established, and a very great change has also taken place in their financial status. What we could not do years ago we can do now. I hope we shall be able to maintain our position, and probably increase our dividend, and if we can maintain it while the bank value of money is going down, I think we shall enjoy the confidence of the investing public.

The proceedings then terminated.

The Monte Video Telephone Company (Limited).

The first annual general meeting of this Company was held on the 18th inst. at the offices, Abchurch-lane, under the presidency of Mr. Arthur Holland.

The SECRETARY (Mr. W. S. Hankey) read the notice convening the meeting.

The CHAIRMAN then said: Gentlemen, it will not be necessary for me to detain you in proposing the adoption of the report. As regards the profit of £10,439, we think it extremely satisfactory, because in the first place this was a new Company which had to contend against the usual dislocations which take place when an enterprise is transferred from one set of managers to another; and in the next place, we suffered in February last from a severe cyclone which occurred in Monte Video. Our wires were damaged very severely, casting considerable expense on our revenue account. Owing, however, to the able way in which our manager, Mr. Arthur Powers, dealt with the matter, the difficulties which he had to contend with were overcome, and he put everything to rights in due course. Comparing our expenses with those of other similar telephonic enterprises, particularly with that at Buenos Ayres, we find that our expenses are only 45 per cent. against 50 per cent., and we think that that is satisfactory considering the state of affairs when we first took over this enterprise.

A SHAREHOLDER: 45 per cent. of the gross receipts?

The CHAIRMAN: Yes, as against 50 per cent. in other cases. As we say in the report, we have written off a small amount for preliminary expenses and a small amount from furniture account, and in a few years those accounts will be wiped out. We have thus a balance of £10,302. 18s. 5d., which we propose should be devoted in the first place to a dividend of 6 per cent. on the Preferred Shares; and, secondly, to place £1,000 to renewal account. We consider that that is only a prudent measure, looking at the nature of this sort of undertaking. Then we propose the payment of a dividend of 2½ per cent. on the Ordinary capital. The £3,000, however, which remains after declaring the 6 per cent. on the Preference Shares is, as you will calculate, almost sufficient to pay 5 per cent. on the Ordinary Shares, but we have considered it prudent to limit the dividend on the Ordinary Shares to 2½ per cent. for the past year, to the 31st of July, and we shall carry forward a balance of £325. We shall ask you to pass a resolution declaring the dividends, and the warrants we propose should be sent out on the 21st inst. As the holders of the Preference Shares know, we have already paid them an interim dividend—in March last. The chief points we wish to call your attention to in this report are—first, the amalgamation with this Company of the Gower-Bell Company of Monte

Digitized by Google

Video, a measure which we considered expedient to take, as it not only consolidates our position there, but also stops any other companies from having a footing in Monte Video. The number of subscribers we gained by that amalgamation has been somewhat disappointing, because when we took over the other concern we found that a great many of the subscribers were duplicates of our own, and they ceased the Gower-Bell subscription when we took them over. Then, we found that a considerable number of them were what we call bad payers, and it was rather unadvisable that we should keep them on. Another point we desire to call your attention to in this report is this—that in order still further to perfect our telephonic system, we have decided, under the direction of our able managers, Mr. Edward Powers and Mr. Arthur Powers, to institute what they call the multiple switch-board. It is believed that this improvement will make the system as perfect as possible, and it will do away with all the annoyance caused by the continual waiting for subscribers to be switched on. The cost of the multiple switch-board will be between £5,000 and £6,000; and we have also had to supply aerial cables, to keep the system in perfect order. This outlay has, of course, run away with a considerable amount, and we have made arrangements for increasing our expenditure on capital account by about £5,000. As regards the multiple switch-board, we find from the experience of others who have adopted it that the number of subscribers at once increased very fast, and if we may judge of the experience of the United River Plate Company of Buenos Ayres, we may expect that our subscribers will increase from 50 to 100 per cent. In the other company, the effect of the adoption of the switch-board was that the subscribers ran up from 2,200 to over 4,000 when they instituted the switch-board. That is what we have heard. The importance of such an increase in our subscribers on our Ordinary Shares will be manifest. We have a large surplus over and above the interest we have to pay on the Preference Shares, and any gain over and above that fixed interest, which we are quite capable of earning at present, will all go to enhance the dividend on the Ordinary Shares. As regards the future, in addition to the increase in the number of our subscribers which we fully expect from the institution of the multiple switch-board, we anticipate a great accession from the "boom" of prosperity which seems at last to have burst upon Monte Video and Uruguay. From reports that have come to hand in the past week, I see that in Monte Video there is not a single house to be let. That means that an extension of building must take place, and with the extension of building there will be an increased demand for the use of the telephone. A study of the trade reports of Uruguay, the centre of which is Monte Video, also shows that the trade of the country increased in 1888 over 1887 by over 30 per cent. I do not know that there is anything else that I have to bring to your notice, and I will therefore conclude by proposing—

"*That the report and statement of accounts now submitted be received and adopted.*"

Mr. THOMAS D. PETERS seconded the motion.

Mr. E. H. WOODS asked how it was proposed to issue the additional capital.

The CHAIRMAN: We have in hand a certain number of Preference Shares unissued, and we purpose issuing a certain number of them. He then put the resolution, which was carried unanimously. Subsequently, he proposed the declaration of the dividends mentioned on the Preference and Ordinary Shares.

The MANAGING DIRECTOR (Mr. Edward F. Powers) seconded the resolution, which was carried unanimously. He afterwards proposed the re-election of Mr. Holland, the retiring Director.

Mr. E. H. WOODS seconded the motion, which was carried unanimously.

The Auditors, Messrs. Gérard Van de Linde and Son, were next re-elected, and the proceedings terminated in the usual manner.

Brazilian Submarine Telegraph Company (Limited).

Report of the directors for the half-year ended 30th June last, to be submitted to the thirty-second ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, the 6th November, at twelve o'clock:—

The revenue for the half-year amounted to £113,083. 6s. 10d., and the working expenses to £13,329. 11s. 9d. After providing £12,880 for debenture interest and sinking funds, and £1,593. 8s. 6d. for income-tax, there remains a balance of £85,280. 6. 7d.; to this is added £20,828. 17s. 2d. brought forward from 31st December last, making a total of £106,109. 3s. 9d. A quarterly interim dividend amounting to £32,500 has been paid, and £45,000 transferred to the reserve fund, increasing that fund to £259,660. 9s. 8d.

The Directors now recommend the declaration of a final dividend of 1s. per share, making, with the interim dividends, a total dividend of 6 per cent. for the year, and also the payment of a bonus of 3s. per share, both free of income tax, which together will amount to £26,000, being a distribution in the aggregate of 7½ per cent. for the year ended 30th June, 1889, leaving a balance of £2,609. 3s. 9d. to be carried forward.

On the 31st July last the sum of £14,500 was transferred to pay off the 145 bonds of the 1884 issue, drawn for redemption in April last. This repayment reduces the debenture debt to £159,500.

The new cable to the Cape of Good Hope *vid* the West Coast of Africa was opened to the public on the 4th June last. Messages to and from South Africa now pass over this Company's lines between St. Vincent and Europe under the arrangement referred to in the last report. The receipts from this traffic justify the expectation of a satisfactory return on the capital invested by this Company in the shares of the African Direct Telegraph Company.

The various sections of the Company's line are in good working order.

The Right Hon. Viscount Monck and the Duke de Loulé retire by rotation at this meeting, and being eligible for re-election as directors, offer themselves accordingly.

The two auditors, Mr. Henry Dever and Mr. John Gane, also offer themselves for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended October 18, 1889, amounted to £4,477.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY.—The directors of this company have declared an interim dividend for the half-year at the rate of 5 per cent. per annum, less income-tax, on the ordinary, and at the rate of 6 per cent. per annum, less income-tax, on the preference shares, the respective dividends to be payable on the 14th of November, the transfer books to be closed from the 25th to the 28th inst., both days inclusive.

EASTERN EXTENSION COMPANY.—This company notifies that the coupon on their Five per Cent. Debentures (1880 issue), due on 1st November proximo, will be paid on and after that date on presentation of the same at the Consolidated Bank, 52, Threadneedle-street, E.C. Coupons must be left three clear days for examination.

TAUNTON ELECTRIC LIGHTING COMPANY.—At a meeting of this company, on Monday, it was decided to increase the capital by creating 2,000 new shares of £5 each. This course had become necessary, it was stated, because of the increased demand for the electric light by consumers, to meet which new plant had to be laid down and larger premises erected.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended October 18, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,990.

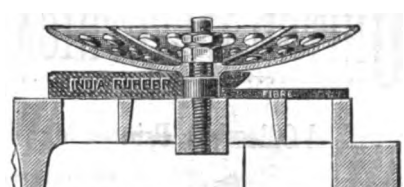
WEST INDIA AND PANAMA TELEGRAPH COMPANY.—At a meeting of the directors of this Company, held on Wednesday, it was decided to recommend to the shareholders at the approaching general meeting that, subject to final audit, a payment of 6s. per share, balance of arrears, and 6s. per share dividend to June 30th last on the First Preference Shares, and 10s. per share on account of arrears on Second Preference Shares be declared, placing £2,000 to reserve, and carrying forward £1,609. The receipts of this company for the half-month ended October 15th amounted to £2,053, as compared with £2,557 in the corresponding period last year, showing a decrease of £504.

CHANGE OF ADDRESS.—The offices of Mr. J. E. H. Gordon, engineer to the Metropolitan Electric Supply Company (Limited), and to the Electric Construction Corporation (Limited), have been removed from 4, Waterloo-place, S.W., to 11, Pall Mall, S.W.

WOODHOUSE AND RAWSON UNITED (LIMITED). — NOTICE OF REMOVAL.—Owing to the large increase in their business, this firm have found it necessary to take more commodious premises, and will next month remove to 30, Cannon-street, E.C.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 598.—Vol. XXIII. FRIDAY, NOVEMBER 1, 1889. Price Fourpence.

NOTES.

We would remind our readers that on Monday next, November 4th, the Institution of Electrical Engineers holds its first dinner, and it is hardly to be doubted that this innovation will be successful and will be continued. The Institution of Electrical Engineers is in this matter only taking one more step in imitation of the older and worthy Society on the lines of which it is modelled, and in doing so it is taking a step in the right direction to draw its members into closer social relations, and render possible more united action. We understand that a number of distinguished guests will be present, and amongst those who we believe have already accepted are the Marquis of Salisbury, the Astronomer Royal, the Hydrographer of the Admiralty, Mr. Courtenay Boyle, Major Marindin, R.E., Dr. Anderson, the Presidents of the Royal Society, the Physical Society, the Institution of Civil Engineers, and of the Iron and Steel Institute.

Whatever may be the outcome of the resolution relating to the forthcoming Exhibition at Edinburgh which was brought forward by Major Flood-Page at the last meeting of the Electrical Trades Section, there can be but little doubt that the time has arrived when some such action should be taken. The day has gone by when the electrical industry existed on sufferance, and when electricians were content to pay heavily for the honour of exhibiting their wares; and if this movement is supported with anything like unanimity, the result can hardly fail to be satisfactory. At the same time, we would remind those who assert that because these Exhibitions bring in no direct increase of business they are therefore useless institutions, that although the direct increase may be infinitesimal, the holding of Exhibitions all over the United Kingdom in which electricity plays so important a part may be indirectly beneficial to the trade. The public is by this means more and more familiarised with the beauty of the electric light and the advantages of electric power—a process which in the long run can only end in increased business. We trust, therefore, that the spirit of compromise will prevail, and that the promoters of the Edinburgh Exhibition of 1890 will see their way to concede any reasonable demand on the part of the electrical industry.

We are glad to see that *The Times* publishes last Saturday a letter, which will be found in another column, from Sir Henry Roscoe stating that the matter of a memorial to Dr. Joule has been taken in hand by the Royal Society, and that a committee has been appointed to deal with the question. The Council of the Royal Society is the chief official representative of British science, and in taking the initiative into their own hands we feel sure that the Council will find themselves supported and strengthened by all those who are in any way anxious that the memory of a great name should be fitly preserved, and honour done to one who has conferred lasting honour on his country and his age.

One memorial which we already possess of Dr. Joule's life-devotion to the pursuit of experimental inquiry is the most valuable volume of his collected papers, published by the Physical Society of London. A glance at the Table of Contents shows the immense range over which Dr. Joule's inquiries extended. His first Paper was communicated in 1838 to Sturgeon's "Annals of Electricity," and describes an electro-magnetic engine, having the field-magnets arranged in a manner not unlike that of a Ferranti alternator, and having an ingenious commutator. Starting from this Paper, there is hardly any portion of the sciences of electricity and heat on which he has not left the impress of his fertile invention and intensely accurate quantitative research.

In one of Dr. Joule's Papers occurs an account of an electric balance in which the stress effect existing between conductors traversed by electric currents is employed to weigh or measure the currents. This fact has, as we all know, been taken advantage of by Sir W. Thomson in the construction of his beautiful ampere-balances.

We publish in another column an abstract of a Paper by Dr. Henry Morton, on the "Energy-Relations of Gas and Electric Lighting." Dr. Morton takes as his means of comparison a 16-candle Sugg-burner consuming 4 cubic feet of gas per hour, and an incandescent lamp of 16 candles yielding 160 candles per horse-power. On the assumption of a 5 per cent. utilisation of the potential energy of the coal by a dynamo and steam-engine, and a waste of 50 per cent. of the same energy in the production of radiant energy by combustion, the author arrives at the conclusion that in producing light from coal, as far as energy waste is concerned, the process of steam-engine, dynamo, and incandescent lamp is about on a par with the

Digitized by Google

process of gas making and gas combustion. We think, however, that exception may be taken to these figures on the ground that an injustice has been done to the incandescent lamp. Good modern incandescent lamps can be worked at a temperature equal to 200 candles light per horse-power, and yet have a fairly long life, and in proportion as the price of the lamps is reduced, it will be possible to run them economically at still higher temperatures. The balance is, then, considerably in favour of the incandescent lamp.

It must not be forgotten that the temperature of the gas flame is not capable of being raised in the same manner in which the filament of a carbon incandescent lamp can be. The value of the incandescent lamp as an energy-translating device increases with the temperature. A valuable Paper on this subject was communicated by Prof. E. L. Nichols, of the Cornell University, to the *Transactions* of the American Institution of Electrical Engineers, in which the luminous efficiency of arc and incandescent lamps is considered, and brought into comparison with gas and other means of illumination, with the result of showing the superior efficiency of the electric incandescence method over those depending on combustion.

The results of experiments with lead-covered and iron-armoured cables which M. Jacquin brought before the Paris Electrical Congress, and which we give in detail in another column, are of importance because showing that, from a practical point of view, there is no appreciable waste of energy from eddy currents and hysteresis when such cables are used for alternating currents. With a lead-covered cable the loss was only 1 or 2 per cent. of the ohmic loss, and with a cable having the usual iron armour it rose to 18 per cent. Under very unfavourable circumstances, when both the lead and iron covering of the out and home cable were connected, the loss was 35 per cent.; but as such a connection can be always avoided, the loss of 18 per cent. of the ohmic loss need alone be expected in practice. This is so small an amount that it may well be neglected entirely.

Our esteemed contemporary, the *Electrical World* of New York, publishes in its issue of October 19th a carefully-compiled list of the electric railways at present in operation or in progress in the United States. The table shows a grand total of 179 roads, 1,260 miles of track, and 11,884 cars, some 113 roads being actually at work. Considering that at the end of 1885 there was only one solitary electric railway in operation, the growth of electric traction has been something phenomenal even for such a go-ahead country as America; and we can only hope that the quality of work done has been equal to its quantity. Not content apparently with this brilliant record, our enterprising cousins are turning their attention to this country. If they succeed in infusing the English tramway companies with some of their own innovating energy, there will not, we venture to say, be a very close scrutiny as to who brought about the desired result.

A fatal street accident caused by an electrical lighting current in New York has revived the crusade against overhead wires, and the business of chopping down poles by order of the Mayor is proceeding vigorously. This does not, however, prevent the erection of new ones—both operations going on simultaneously, and apparently under sanction of some contradictory legal rulings. Nevertheless, in the present temper of the New York public, rendered very excited by the painful incident reported in our American correspondent's letter this week, it is almost certain that a large number of wires will be added to the underground conduits, and that these receptacles will be increased and extended. The result will be watched with great interest in this country, not less than in the States, especially through the winter months, when the wires will be put to their severest strain, and the efficiency of the conduits tested to the utmost.

We have heard so much about the danger which in New York and other American towns arises from infiltration of gas into electric light conduits, that the fact of a similar phenomenon having been observed here is well calculated to cause alarm. Apparently the Strand District Board only concerned itself with the question of inconvenience arising from the escape of gas by means of an electric light conduit into a house in Norfolk-street; but the matter has a far more serious aspect, for an explosion might at any time occur. If we remember rightly, infiltration of gas into the large conduit carrying the electric light mains over the Kensington Court estate at one time caused some difficulty, and special precautions had to be taken to keep the conduit thoroughly ventilated. It is important to note that the danger increases with the size of the conduit. The quantity of gas which can accumulate in a small iron pipe partly filled with conductors may, perhaps, be insufficient to explode with destructive effect, to say nothing of the greater ease with which a small pipe can be kept tight; but when it comes to the employment of large brick culverts, both the difficulty of preventing infiltration and the destructive effect of an explosion are greatly enhanced. Now brick culverts are used in order to avoid the necessity of insulating the conductor, which in this case is composed of bare copper strip. The absence of insulation, again, renders the occurrence of a spark, which might fire the explosive mixture, far more likely than when the mains are properly protected, so that this system of mains, which now seems a favourite one with several companies, would hardly appear so safe as in the interest of electric lighting is desirable. It would, at any rate, be wise to defer its wholesale adoption until prolonged experience has proved that the danger to which we have alluded can be effectively guarded against.

In the letter on electric traction which will be found in our correspondence columns, Mr. W. D. Sandwell takes up the cudgels in defence of his "system" of electric tramcar. His arguments amount briefly to this: The cells require over 38 square feet of floor space, and only 33 square feet are available under the seats; cells which can be accommodated in the smaller space have not enough storage capacity; a spare

Digitized by Google

armature is a very handy thing, and to employ two motors on the same car is an absurdity, because the cells cannot supply current to both at the same time. Taking the last point first, our correspondent seems to be under the impression that where two motors are employed the object is to work them in parallel when starting and when a spurt is required. This is not so. The two motors are coupled in series on starting and on heavy gradients, and in parallel when running on the level at full speed. If used in this way, the effect of the arrangement is exactly the opposite of that ascribed to it by our correspondent. The strain on the battery is relieved, and not augmented, at starting. His contention that a spare armature is a necessity is contradicted by the practical experience gained in America with electric tramcars and by English experience with dynamos. There are many ship-lighting dynamos which are kept running for weeks together without a moment's stop, and yet their armatures do not break down. As regards the want of storage capacity, this has never been a trouble: the real difficulty is the limited rate of discharge, and this can only be overcome by an improved construction of cells—not by the way they are placed. Taking our correspondent's figures, we find that he can with his tender employ 15 per cent. more battery-power, as compared with the usual arrangement of putting the cells under the seats. This 15 per cent. is, however, not a clear gain, for we have to move the additional weight of the tender; and after making allowance for the extra resistance of four more wheels, especially on curves where the tender will be dragged to one side, the margin left is so small that a very trifling improvement in the batteries themselves will bring the balance even, to say nothing of the almost fatal objection to the greater length of his arrangement.

It was with justifiable pride that Mr. Massingham, in addressing a meeting of the shareholders of the Taunton Electric Lighting Company last week, referred to the continued prosperity of the Company. The Taunton station is, of course, a very small affair when compared to many on the Continent and in America, but its record is one which it would be difficult to surpass. How greatly the success at Taunton has contributed to the advancement of electric lighting in this country may, we think, be fairly gauged by the fact that in almost every instance where an Electric Lighting Committee has reported in favour of a Municipal station, they have justified their recommendation by what they had seen or by what had been done at Taunton.

The Conference of electrical workmen, commented upon in these columns a fortnight ago, is developing into an "Operative Electricians' Union," which is to embrace all telegraphic, telephonic, and electric-lighting workpeople in the kingdom. A meeting pledging itself to support this Trades Union was held in the Albion Hall, London Wall, last Saturday night; and although the real origin of the movement was, like its real object, left in vague uncertainty, the crowded audience lost no time in being enrolled as members. Of course the inevitable Member of Parliament was present, and of course he told them that they ought all to join the Union, although "he did not know whether they had any grievances to complain of." This over-candid friend—Mr. J. Rowlands, M.P.—also counselled them to have nothing to do with "outsiders," a piece of advice which, after listening to him, the meeting perhaps wished they had followed a little earlier. We, also, are not aware that there are any legitimate grievances which electrical operatives could not redress by less costly means than the support of a Trades Union, and we suspect that "outsiders" like Mr. Rowlands encourage such organisations quite as much for political as for industrial purposes. But that is the workman's affair, and as he seems to know no better, while nobody has the courage to enlighten him, we can only leave him to his own devices.

We regret to hear that the publication of the *Fortschritte der Elektrotechnik* is likely to be discontinued, as it has not met with sufficient support to make it a financial success. We would suggest, however, that if the *Fortschritte* were published annually in lieu of quarterly, not only would the labour, and consequently the cost of preparation, be considerably lessened, but the volumes would be handier and less expensive—without, we think, being appreciably diminished in value.

A Spanish Cable.—The Spanish Government have obtained a concession for laying a cable between Algesiras, Tangier, Ceuta, and Melilla.

Belgian Exhibition in London.—It has been decided that the fourth in the series of National Exhibitions at Earl's-court shall be a Belgian one.

Lighting of Cadiz.—We understand that the specification and conditions of tender for the lighting of the city of Cadiz by electricity are now published.

Portrait of the late Mr. La Trobe-Bateman.—We learn that Messrs. Morris and Co., of 392, Strand, are about to publish, by permission, a portrait of the late Mr. La Trobe-Bateman.

Birkenhead—The minutes of the Finance Committee of the Town Council, recommending that a Provisional Order should be applied for, were confirmed at the last meeting of the Council.

Electro-Harmonic Society.—A smoking concert will take place this (Friday) evening, at St. James's Hall Restaurant, Regent-street, W., at eight o'clock. An excellent programme is provided.

The Electric Lighting of the Yldiz Palace.—MM. Sautter, Lemonnier et Cie. have undertaken the lighting of the Yldiz Palace at Constantinople on the occasion of the visit of the Emperor of Germany.

Electricity in Brazil.—Rio advices report the formation of an electrical company at São Paulo, under the title of the "Companhia Electrica de S. Paulo." The capital is 80,000 milreis, in 1,600 shares of 50 milreis each.

The Telegraph Construction and Maintenance Company.—It is announced that Sir George Elliot, M.P., has been elected Chairman of the Telegraph Construction and Maintenance Company (Limited), in place of the late Sir Daniel Gooch.

Exeter.—The Town Council have instructed the city surveyor and superintendent of the fire brigade to report on the position of the electric light wires and posts in the streets of the city, especially in relation to the extinction of fires.

Leeds.—The Electric Lighting Committee of the Corporation, at a recent meeting, decided to proceed at once with the lighting by incandescent lamps of the rate office in the municipal buildings, and also of the offices of the police department of the Town Hall.

Digitized by Google

Cork.—A Special Committee of the Corporation, having acquired information, is unanimously of opinion that it would not be in the interest of the ratepayers that the Corporation should themselves apply for a License or Provisional Order to supply electricity.

Paris Exhibition Awards.—The *Journal Officiel* of Oct. 20 contains a list of the awards granted to the principal *collaborateurs* of the firms who contributed to the success of the Exhibition. Silver medals were awarded to Mr. F. V. Andersen (Latimer Clark, Muirhead and Co.) and to Mr. Spratt (Elliott Bros.).

Bournemouth.—A deputation from the Brush Electrical Engineering Company waited on the Lighting Committee of the Bournemouth Commissioners a few days since, with a view of explaining this company's proposals with regard to Bournemouth, where the Brush Company have a 2,000-light plant already at work.

Newcastle.—The two electric lighting companies have been unable to commence operations on account of a technical point of law, which awaits the decision of the law officers of the Crown. Until this point is settled, the Board of Trade cannot grant the licenses, and, of course, meantime the companies are absolutely powerless.

Concert at the Edison-Swan Works.—The first of a series of concerts to be held this winter was given at the Edison-Swan Company's Works, Ponder's End, on Wednesday evening, 23rd inst. A good programme was provided, concluding with an interesting comedietta. Mr. Edward Gimingham acts as secretary to the concert committee.

Plymouth.—A meeting was held at the Athenæum, Plymouth, on Monday afternoon last, to discuss the desirability of giving to the three towns of Plymouth, Stonehouse, and Devonport the advantage of an electric supply. The meeting was addressed by Mr. Bingham and Mr. Lowrie, of the House-to-House Electric Supply Company.

Brazilian Purchases of Telegraphic Apparatus.—Rio advices of October 7th state that as a beginning towards the proposed addition to the capacity of the State telegraph lines, the Director-General of that service has ordered from Europe some 16,000 kilometres of wire, 14,000 insulators, and 240 instrumenst—the whole to cost about 350,000 milreis.

The Leeds Electric Lighting Report.—It is a somewhat curious fact that the Nottingham Corporation, having at their own expense and with sanction obtained copies of the Leeds Electric Lighting report, decided, after carefully considering the arguments used therein, to apply for a Provisional Order, the Leeds Corporation, on this same report, refusing to apply.

The Blenheim Telephones.—We have received from Messrs. Blenheim and Co., of Egham, Surrey, a copy of their latest catalogue, in which is given an illustrated list of their telephones, bells, fire alarms, indicators, &c. The catalogue contains a long list of users of the telephones made by this firm, and from the testimonials given the instruments appear to give general satisfaction.

The Electric Light in Railway Trains.—A special train, lit by electricity, was run on Saturday by the Cheshire lines Committee, from Liverpool to Manchester and back. The system employed was that of Mr. Radcliffe, telegraph engineer to the Great Northern Railway. The light gave general satisfaction, and its immediate introduction into the regular express service was decided upon.

Eastbourne.—At the last meeting of the Town Council the General Purposes Committee reported that a letter had been received from the Eastbourne Electric Light Company, enclosing for submission to the Corporation a draft of the Provisional Order which the company proposes to apply for. The Committee recommended that a special meeting of the Council should be held on December 2nd, to consider the question.

Hackney District Board of Works.—At the last meeting of the Board, the General Purposes Committee reported that they had had under consideration, notices from the following electric lighting companies of their intention to apply for Provisional Orders:—Sydney Moorse, the House-to-House Electric Light Supply Company, the London Electric Supply Corporation, the Electric Construction and Maintenance Company, and the Metropolitan Electric Supply Company.

An Electric Motor Installation.—A factory covering a considerable extent of ground, and five stories in height, is being built at Leeds for the firm of J. and W. Campbell and Co., of Glasgow. In this building there will be about 800 sewing-machines, as well as the necessary number of cutting-machines to keep these going; all of them will be operated by electric motors. The contract for the electrical equipment has been given to Messrs. McCulloch, Sons, and Kennedy, of Kilmarnock.

Birmingham.—According to the *Birmingham Post* of yesterday, Messrs. Holmes and Vaudrey, of Liverpool, have arranged with Messrs. Chamberlain and Hookham to purchase their interest in the Provisional Order recently obtained by them for a comparatively small sum, with a view of transferring the Order to a company which is about to be formed. An influential directorate is in course of formation, and the capital of the company will be in excess of the minimum fixed by the Order.

Electricity in the Nizam's Dominions.—The Chudderghaut Municipality have received a proposal from the representative of Messrs. Siemens Brothers, of London, to light the whole of the streets within the municipal limits for a yearly payment of 11,000 rupees. The firm offers to put up 13 lamps for every 20 at present in use lit with kerosine. If the terms are accepted the municipality would effect a saving of between 3,000 and 4,000 rupees a year, besides having the streets much better lighted.

An Improvement in Primary Batteries.—We understand that a Mr. Harris has recently made an improvement in the nitrate of soda battery. Contact screws are avoided by connecting elements in series at the base of the cells, and corrosion of the contacts is thus obviated. The result of Mr. Harris's labours has been the production of a portable lamp suitable for use in mines, &c. The advantages claimed for the new battery and lamp are numerous, but we hope before long to put our readers in possession of more detailed information.

The Telephone in East Kent.—The whole of East Kent is being gradually brought into telephonic communication by the operations of the South of England Telephone Company. Dover, Folkestone, Canterbury, Faversham, Margate, Ramsgate, and Sandwich have had exchanges for some time, and now the company have extended their line to Hythe and Sandgate. Exchanges were opened in these two places last week, and subscribers can speak to Dover and the other towns mentioned. It is intended ultimately to place East Kent in communication with the metropolis by means of a trunk line.

Electricity in Works and Mills.—In the course of a Paper on "The Application of Electricity to Works and Mills," recently read by Mr. T. Vaughan Hughes to the South Staffordshire Institute of Iron and Steel Works' Managers, at Dudley, the reader said that there was everything to recommend an electrical transmission plant. Waste heat from blast furnaces could be used miles away, steam boilers could be placed near the colliery to save haulage of coal, the power of a stream or river could be used, and hundreds of horse-power could be conveyed along small copper wires, whilst the places could be lighted up by electricity. All this could be done well and cheaply.

Monte Video.—The central station of the Compañia Nacional de Luz Electrica, at the Arroyo Seco, Monte Video, was recently inaugurated with considerable ceremony. The building is 77 metres by 51. The 300 horse-power boilers, five in number, are on the Belleville system; the machinery is all from Ganz and Co., of Buda-Pest, and comprises eight 150 horse-power engines and eight Zipernowsky alternators of 150 horse-power each, driven direct. The primary pressure is 1,800 volts, the secondary 100 volts. The present capacity of the station is equal to 15,000 16 candle-power lamps. The lighting of the new city has already made great progress, and every week new districts will be added till the service is completed through both the new and the old city, in all about 5,000 lamps will be required.

The Electric Light in the Royal Navy.—During the recent naval manœuvres it was found that the search lights on ships

Digitized by Google

of the M class were awkwardly placed. The Admiralty has, therefore, decided to adopt the suggestion of Captain Wilson, of the "Vernon," with the view of remedying the defect. In place of the towers, which are very inconvenient, owing to the seas breaking against them, a portable platform will be shifted inboard, so that the electric light may only be used when actually required. This arrangement will give the ships extra stability, and the search lights will not be too much in evidence during an action. The new plan is shortly to be tried on the "Marathon" and "Magicienne."

Bradford.—At a special meeting of the Town Council on Saturday an additional sum, amounting to £25,000, was granted to the Gas and Electric Lighting Committee in order to enable them to complete the works begun, and also to enable them to meet the extra and unexpected demand for the supply of the electric light. The chairman of the committee (Alderman F. Priestman) stated that the committee had no intention of spending the additional sum of £25,000 at once, but it was necessary to have a smaller sum of, say, not less than £10,000 wherewith to carry on the branch already established. Their present borrowing powers were £20,000, and that sum had been slightly exceeded. He gave the Council a pledge that nothing more should be expended beyond what was required to carry on the present installation without a special resolution of the Council.

Cambridge.—At the last meeting of the Cambridge Improvement Commissioners the electric lighting report of the Joint Parliamentary, Paving, Drainage, and Lighting Committees came up for consideration. The report, which was of great length, concluded by recommending that the Commissioners should themselves apply for a Provisional Order, and that the alternate-current transformer system should be employed. The report was adopted unanimously. Mr. Ferranti sent in an estimate for a 9,000-light station, building, plant, and mains complete for £25,000, at the same time advising the Committee to start with a 6,000-light station, costing £19,000. From the latter, he estimated, on the basis of all the lamps being taken up and burning on the average three hours per day, that an annual income of £7,666 would be derived, yielding a profit of over £2,000.

Great Yarmouth.—Mr. Cockrill, the borough surveyor, has submitted a report to the Town Council relating to the electric lighting of the borough. Since making his last report Mr. Cockrill says that he has received an offer from a firm of electricians to put in an installation and supply electricity at 3¾d. per Board of Trade unit, equal to gas at 3s. 3d., this price to include all interest, capital charges, and allowances for depreciation. The report then proceeds as follows:—"I would urge upon the Council that it is advisable that they should seek to obtain powers themselves, and that such powers should extend to the whole of the borough. My opinion is that a small installation could be commenced, providing for lighting the busiest portion of the town. If properly designed such an installation as I have sketched out could gradually be extended and would pay its way."

Stafford.—A special meeting of the Town Council was held on Tuesday last to receive the report of the Special Committee on the question of electric lighting. Alderman Peach (chairman of the committee) moved that consent be not given to the Provisional Order of the Midland House-to-House Electricity Company, and that application be made for the granting of a Provisional Order authorising the Corporation to erect electric works. They had a capital at stake at the gasworks of about £85,000. Under these circumstances it would be suicidal to allow any company to come and share the profits derived from lighting. If their business at the gasworks increased in the same ratio they would be compelled in the near future to spend something like £15,000 to increase their accommodation, and it seemed to him more desirable to spend the money in providing an electric installation. The resolution was carried, and an Electric Lighting Committee was appointed to take the necessary steps to give it effect.

The "Local Authority" under the 1882 Act.—The Electric Lighting Act of 1882 gives the "local authority" power to give or refuse assent to the application of a company for a Provisional Order, and also to make an application on its own account. The schedule as to the Act mentions three "local authorities": (1) the Town Council; (2) the Police Commissioners; (3) "places within the jurisdiction or limits of any public commissioners or board (other than any of the bodies hereinbefore mentioned) charged by any local Act with the duty of lighting the district within their jurisdiction or limits with gas." The question has arisen in connection with the electric lighting notices in Edinburgh, who, in the case where there is a legally-appointed Gas Commission, is the local authority"? The Lord Advocate for Scotland has recently given an opinion to the effect that the Town Council, as Police Commissioners, is the "local authority" for Edinburgh, implying that the Edinburgh and Leith Gas Commissioners have nothing to do with it.

St. Elmo's Fire on Ben Nevis.—In a Paper on "St. Elmo's Fire on Ben Nevis," by Angus Rankin, in the *Journal* of the Scottish Meteorological Society, it is stated that St. Elmo's Fire as seen occasionally at the Ben Nevis Observatory takes the form of jets of light on the tops of all objects that stand any height above the general level of the roof of the Observatory. In a very fine display the tops of the objects are quite ablaze with the light, which then glows and hisses in brilliant tongues of white and blue from four to six inches in length. Nor is the phenomenon confined to these objects alone in the finer displays, but if the observer stands on the roof, his hair, hat, pencil, &c., glow with it as well, and when he raises a stick above his head the stick has also a long flame at the top. Further, however, than having a slight tingling in his head and hands he suffers no inconvenience. The hissing is a very marked characteristic of the phenomenon, being always heard during ordinary displays, though in the feebler displays, when the light can barely be seen, it cannot be distinguished from the hissing of the wind and the snow drift.

A Private Central Station.—The residences of Mr. Peter Denny, the senior partner, and of six other partners, in the well-known Dumbarton shipbuilding and engineering firm of Denny and Co., are about to be fitted throughout with the electric light. Helenslee, Mr. Denny's mansion, and the other six houses, are all of considerable dimensions, and are situate in the same neighbourhood. The generating plant for supplying the necessary current will be located in a central station, and will consist of a Willan's triple expansion engine coupled direct to a Siemens' shunt-wound dynamo. This dynamo will charge three sets of E.P.S. storage batteries of 54 cells each. The batteries alone will be capable of supplying current for 300 20-candle lights, and if the engine is kept running at the same time a total of 600 such lights can be supplied. As in house lighting rarely more than half the total number of lights are used at one time, this station will, in all probability, be large enough to supply the whole neighbourhood, which consists of between twenty and thirty large houses. The contract for the lighting of the residences has been placed with Messrs. Muir, Mavor and Coulson.

The Taxation of Machinery.—A meeting of manufacturers in the Stroud district was held at the Imperial Hotel, Stroud, on Friday, to hear an address by Mr. Humphreys Davies, of London, the secretary of the National Society for the Exemption of Machinery from Rating, and to discuss the formation of a local branch. The chairman pointed out the importance of the crisis at which the question had arrived, and Mr. Humphreys Davies proceeded to explain the objects of the society and the steps which were being taken to perfect its organisation throughout the country. He stated that the promises of both parliamentary and pecuniary support were most encouraging, and that there was every reason to believe that before the final decision of the House of Lords could be given on the Chard appeal, the Bill promoted by the Associated Chambers of Commerce for the exemption of machinery would be passed. It was also stated that it was intended to raise a guarantee fund of at least £50,000, and that the success of the attempt was practically assured owing to the energetic manner in which the Chambers of Commerce branch associations in all the manufacturing centres had taken the question up. A number

Digitized by Google

of similar meetings are being held throughout the country. The central offices of the society are at 22, Buckingham-street, London, W.C.

Gas in Electric Light Mains.—At the last meeting of the Strand District Board attention was called by Mr. Cole to the state of Norfolk-street. It was not very long ago that this roadway had been repaired, and now it was taken up again. Why was this done? The Surveyor said the position of things was this: the gas company had carried out their works before the electric lighting company had commenced laying their mains. The electric lighting company laid a hollow pipe through the middle of the street, and the joints not being well made, the gas from the gas company's pipes made its way into the electric main, and then found its way into one of the houses, No. 4, Norfolk-street. He had written to the gas company telling them that the Board would require them to watch the work for a period of six days after the pipes were laid. Mr. Cole thought the gas company should be compelled to do the utmost that the surveyor required. Mr. Fowler said it was a matter worthy of full consideration. He knew that the gas escaped continually from the gas mains, and the Board or some authority should adopt some means to prevent this general escape of gas. He could not see why the pipes of the electric lighting companies should not have their joints properly made. Ultimately the subject was referred to the Works Committee.

Magnetic Leakage in Dynamos.—The following is an abstract of a Paper on Magnetic Leakage in Dynamos, read by Prof. H. S. Carhart, of Michigan University:—Two dynamos of the Mather and Edison type respectively were tested; the former was a small machine of 500 watts capacity, built by a student in the laboratory, the latter an Edison of 5,000 watts capacity. In the small machine the leakage was due to some projecting machine steel studs which carried the armature yokes. The number of magnetic lines cut by the armature when the machine was coupled as a self-exciting shunt dynamo was determined, and then the steel studs were replaced by brass and the determinations were repeated. The result was 190,000 and 252,000 lines of force respectively, or a gain due to removing the steel studs of 32·6 per cent. This was partly due, however, to increase in the field when the leakage was stopped. Hence the machine was independently excited by a storage battery, and the number of lines determined in the two cases as before. The result was 164,600 and 184,100 lines cut by the armature with and without steel studs, a gain of 11·2 per cent. The leakage in the Edison machine was due to the iron bed plate. A plank base was made, and the number of magnetic lines cut by the armature was determined, first with the iron base and then with the plank, the machine being self-exciting and running at the same speed in the two cases. The number of lines was 1,510,000 and 1,605,000, a gain of 6·25 per cent. due to removal of the cause of leakage.

Military Telegraphy.—A Paper was recently read before the Aldershot Military Society, upon "The Field Telegraph and its Relation to Military Operations," by Col. Jelf, who lately commanded the Telegraph Battalion of the Royal Engineers. Col. Jelf stated that the two divisions forming the Telegraph Battalion, assisted by their reserve, are calculated to be able to provide for a head-quarters and eight sections—that is, for 800 miles of communication, the allowance for two army corps—while two sections, with 200 miles of telegraph, would be ready to start in 48 hours after receipt of the order to mobilise. Each section carries only 20 miles, but its reserve of 80 miles, with all poles, apparatus, stationery, &c., is kept ready packed at Woolwich, and ready to be put on board transports at the shortest notice. Having gone thoroughly into the subject, and dealt with the tactical advantages and disadvantages of telegraphy in war, Col. Jelf concluded by stating that, having had opportunities of inspecting the field telegraph equipments of the great military Powers and comparing them with our own, he was perfectly satisfied that in telegraphy the British Army was more than holding its own, and he had every confidence that the Telegraph Battalion would prove worthy of the traditions of its short but not inglorious past. Subsequently, Capt. Glen, of the Inns of Court Rifles, submitted a scheme for a light field telegraph to be used instead of visual signalling, which may frequently be read by an enemy from a distance, besides being slow in operation, greatly dependent upon weather, and laborious.

French Tramway Statistics.—Up to the end of 1888 the total length of tramways for which concessions had been granted stood at 789 kilometres, including those lines worked by animal and mechanical power. In the first class of tramways, namely, those worked by animal power, 590 kilometres are included, leaving only 199 kilometres as worked by mechanical means. Out of the 789 kilometres conceded, 743 kilometres were being operated at the end of the year. Tramway communication has reached the highest point of development in the Department of the Seine, where there are laid 252 kilometres on which animal power solely is used, it being stated that the trials made with mechanical traction have been unsuccessful, and consequently abandoned; this, however, not applying to electrical power, which has been tested and reported to have given good results. On an average, it may be stated, that the cost of lines for animal-worked trams has been £7,200 per kilometre, whilst for mechanical traction the lines of the Loire and St. Etienne cost only £6,000, those of the Nord from £3,280 to £3,440, and of the Sarthe £2,640 per kilometre. A comparison of the costs of working of the animal and mechanically drawn tramways is still more favourable to the latter. An examination of the detailed accounts shows the Parisian animal-drawn trams use up on the average for all lines about 90 per cent. of the gross receipts, whilst over the whole system where animal power is in use the average may be taken at 80 per cent. Grounding its opinion on the statistical proof of the superiority of the return from the tramways using mechanical power—and admitting that electricity may be requisite in Paris itself—the *Journal des Transports* hopes for a considerable extension of its use instead of animal force, and regards inter-urban communication of this kind as the most likely to afford immediate profits.

The Operative Electricians' Union.—A crowded meeting of the *employés* of electric lighting, telephone, and telegraph companies was held on Saturday night at Albion Hall, London-Wall, in support of the newly-formed Operative Electricians' Union. The chairman (a London electrical operative) explained that at a recent conference held in London of 300 men employed in telegraphy (mostly in the service of railway companies), electric lighting, and the telephone industry it was decided that it was quite time a trade union should be formed, not for aggressive purposes, but for the protection of the interests of the immense and constantly increasing number of workers in all branches of electricity. It was intended to have an organisation for the whole of the kingdom, based upon the most approved trade union lines, and governed by one code of rules hereafter to be determined by a representative conference. The movement had originated at Manchester, and was spreading to Liverpool, Glasgow, and most large provincial cities and towns. Mr. J. Rowlands, M.P., who had been invited to address the meeting, said he understood there were in London alone 3,000 operative electricians of various kinds eligible as members of their union, and he hoped they would all join it. Their industry, which was of comparatively new growth, was likely to be the great industry of the near future, and it behoved them as prudent men to have an association for the protection of their legitimate and just interests. He did not know whether they had any grievances to complain of, but if they were satisfied with their present remuneration they would be better able to maintain it by their organisation. He counselled them to have nothing to do with "outsiders" in the control and management of their affairs, but to select the best men from amongst themselves to form the executive of their union. He advised an amalgamated society of all branches of their trade for the entire kingdom, and suggested that they would do well to see how far they could profit by following on the lines laid down by the best managed and most successful of existing trade unions. The meeting pledged itself to support the new union, and most of those present who had not already joined enrolled themselves as members.

A COMPARISON BETWEEN THE CONTINENTAL, AMERICAN, AND ENGLISH DYNAMO-ELECTRIC MACHINERY.

BY ALBION T. SNELL.

The following paper has been suggested by a visit to the Paris Exhibition. It is not intended to strictly confine the comparison to machines exhibited there, however; for, by so doing, the bulk of the English machines would be *hors concours* by reason of their absence. Yet, the greater part of the American, and the whole of the Continental firms referred to, are represented in the "Exposition."

It is in the domain of heavy electrical engineering that one is most impressed with the progress made on the Continent. Within the confines of the Exhibition there are no less than six central stations distributing power and light, and each counts its horse-power by the hundred. The "Société pour la Transmission de la Force par l'Electricité," the "Compagnie Continentale Edison," the "Société Alsacienne," the "Société Gramme," Messrs. Steinleu & Co., and the Oerlikon Company have all large plants for power and light. The aggregate power is probably more than 3,000 indicated horse-power. These installations are small compared with many in various towns, but regarded as exhibitions they are sufficiently remarkable. Owing to the fact that a large portion of the output is used for electrical transmission of power, the dynamos are chiefly of the direct-current type. Indeed, the brake horse-power of the electric motors, running in the different courts, is probably in excess of the total electric-motor power of Great Britain. That electric transmission of power does not seem to make much progress at home is an unfortunate fact, probably explained by the low price of gas and coal, and the absence of suitable water-power in most of our manufacturing centres.

English engineers will thus do well to study the power plants as exemplified at the Exhibition. There are many points developed by the extended practice of the Continental electricians, and much may be gained by an unprejudiced examination of the general details.

Broadly viewed, the Continental dynamos and motors are of sound design. Theoretical principles are properly appreciated, and the mechanical construction shows engineering of the highest order, though not always in accordance with our notions. In most cases, too, a sense of the beauty of proportions is evident, many of the designs being even elegant. Metal is used in the right place, as a rule; and, with few exceptions, the winding and other details are well carried out. To this general criticism some exceptions may be made, and very big ones too; but, on the whole, the dynamos compare very favourably with those in the English and American markets.

Generally there seems to be a tendency towards multipolar direct-current machines on the Continent: witness the Oerlikon (*Electrician*, July 19, p. 270), Thury-Alioth (*Electrician*, August 23, p. 397), Marcel-Deprez, Jaspar and Henrion exhibits.

In England, with the exception of the Brush and Gülcher Companies, and Messrs. Elwell-Parker in their larger dynamos, the two-pole type seems to be most favoured. I think, however, not always wisely. There seems to be a certain maximum width of pole which gives the best results for a given weight of material. Without entering into a theoretical discussion, I believe that practice has shown this to be the case. Indeed, my own experience points in this direction, and a careful comparison of weight efficiencies of a few large machines will justify the statement.

The "Continentale Edison," the "Société Gramme," and the "Société Alsacienne," however, use large two-pole machines, with single magnets. The Edison Company's machines have drum armatures and wrought-iron magnets with the cores and yoke above the armature. This form of field is similar to that originally adopted by Edison, but the modern forms, however, all embody the improvements suggested by Hopkinson with reference to length and cross-section of the cores. The chief advantage of this type of field would seem to be the small quantity of copper required in the windings. There are several disadvantages inherent to the single horse-shoe magnet, and these increase in their relative effect as the dimensions of the machine are increased. Primarily, there is a tendency to irregularity of distribution of the magnetic flux, causing a pull on the armature in the direction of the yoke. There is also a difficulty through heating with large armatures working with high magnetic densities, such as usually obtain with two-pole machines, about 16,000 to 18,000 C.-G.-S. units. Better results will be given by multipolar fields and lower densities.

With very large machines this inequality of field may assume such proportions as to render it practically impossible to keep the bearings cool, unless special precautions are taken. The Edison type of single magnet is the least affected by this, since the weight of the armature is against the attraction produced by the unequal field. This evil can also be counteracted to some extent by placing the armature excentric to the bore of the pole-pieces. A drum armature will give better all-round results in such a field than the ring type, since the field distortion will be generally less.

The Alsacienne machines (Fig. 1) are of the drum type, with the single field inverted, *i.e.*, the yoke is formed in the bed. As might be expected, the difficulty mentioned above appears here with greater force, for the weight of the armature is acting in the same direction as the distortion of the field. The result is a more or less heavy strain on the bearings. It is not surprising to find that the company have found this so, and have only overcome the difficulty after some considerable experimenting. In one case they found the downward pull on the shaft amounted to 1,500lbs.

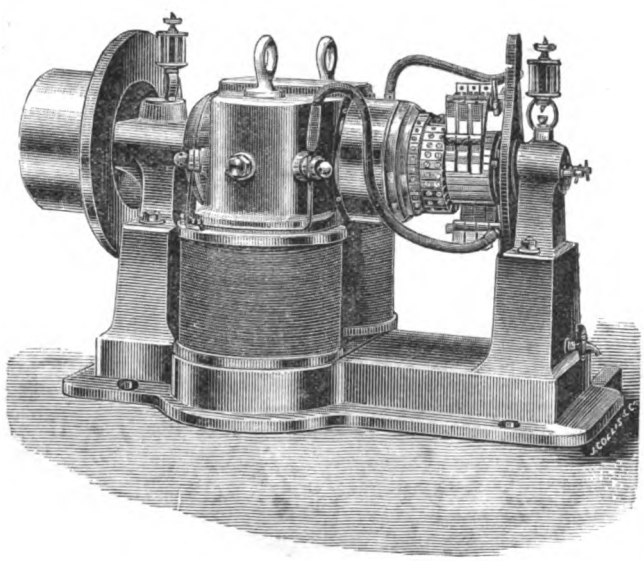

FIG. 1

I have myself seen a 3½in. shaft deflected $\frac{1}{16}$th of an inch in such a field. The Alsacienne engineers have overcome this difficulty by making massive pole-pieces with wrought-iron cores, thereby increasing both the cost and weight of the machine.

Messrs. Paterson and Cooper have built a number of machines of this type, but I believe they have not exceeded 16in. for the diameter of the armatures. The "Kapp" dynamo is also built on these lines.

The Gramme Compagnie have, perhaps, still more unfavourable conditions to contend with. They have the inverted single magnet and a ring armature. They overcome the downward strain by wrought-iron pole pieces bolted to the inside of extensions of the cast-iron magnet cores. Probably the armature is excentric to the pole-pieces, *i.e.*, the centre of the shaft is raised above the median line of the field-bore. Messrs. Siemens and Halske, of Berlin, have also made machines of the inverted single magnet type, but I do not know with what success.

In judging the relative merits of a design, one must not be content with the bare statement that the type runs successfully. Any motor, and nearly any dynamo, will run, and

Digitized by Google

with proper management may generally be made to run well. The questions to be especially considered in forming an opinion are cost of production, including weight efficiency, durability, and cost of maintenance.

In England some of the disadvantages of the Edison type of machine are got over by using a frame-shaped bed with the pole-pieces sunk into the centre hollow and secured against brass distance pieces. The armature is thus very low down, nearly half being below the top of the bed. The drum type finds general approval for this class of dynamo. Machines of this type, with various modifications, have been built by Messrs. Latimer Clarke, Crompton and Co., and Messrs. Siemens Bros. They seem to be chiefly used for central station work.* With armatures of medium size there would appear to be little objection to this type; but with large armatures, say 24in. in diameter, I expect the field would be unequally distributed and cause trouble. The weight efficiency is probably raised above that of the other single magnet types.

For large two-pole machine a double field-magnet is preferable from some points. The distribution of magnetism in the armature is more regular, and there is some gain in weight efficiency. Machines of 50,000 watts and upwards have been built on these lines by Immisch and Co. (Fig. 2) for transmission of power in mines, and also for lighting and charging accumulators. Messrs. Mather and Platt have also identified themselves with this design in their well-known "Manchester" (Fig. 3) dynamo. Numerous other makers in England, America, and the Continent have also adopted this type. (In general all these machines have a very large waste field, which, though of no practical importance in most cases, is inadmissible for ship lighting. A single magnet with the armature sunk into the bed, as in the "Westminster" machine, is the least likely to give trouble aboard ship.)

But, on the whole, I do not think that large machines of the two-pole type would give such good all-round results as can be obtained from multipolar machines, especially if these latter have disc armatures. It seems remarkable that disc armatures have not found more favour for continuous-current machines. They answer admirably for alternating generators, and for synchronous motors. They are light, not exceptionally difficult or costly to construct, and are capable of a very large output per pound of material. If very large continuous-current dynamos are in demand, I expect the near future will see disc armatures of large diameters, with massive stationary magnets. The difficulty attending the coupling of the coils is not insurmountable. As a step in this direction, I may cite the short cylinder armatures of large diameter used in the Victoria and Gülcher dynamos, and more recently in a similar type by Messrs. Ernest Scott and Co. (see *Electrician*, October 4, p. 547). These machines all have shrouded pole-pieces. The above-mentioned advantages do not appear to be very apparent with the smaller sizes: indeed, my own experience points to a diminution of output. The ordinary cylinder or drum seems to give the better results for small outputs. I have never heard of a very large armature of this type—say, with 12 or more poles, and a very narrow core—but I expect the results would be very satisfactory.

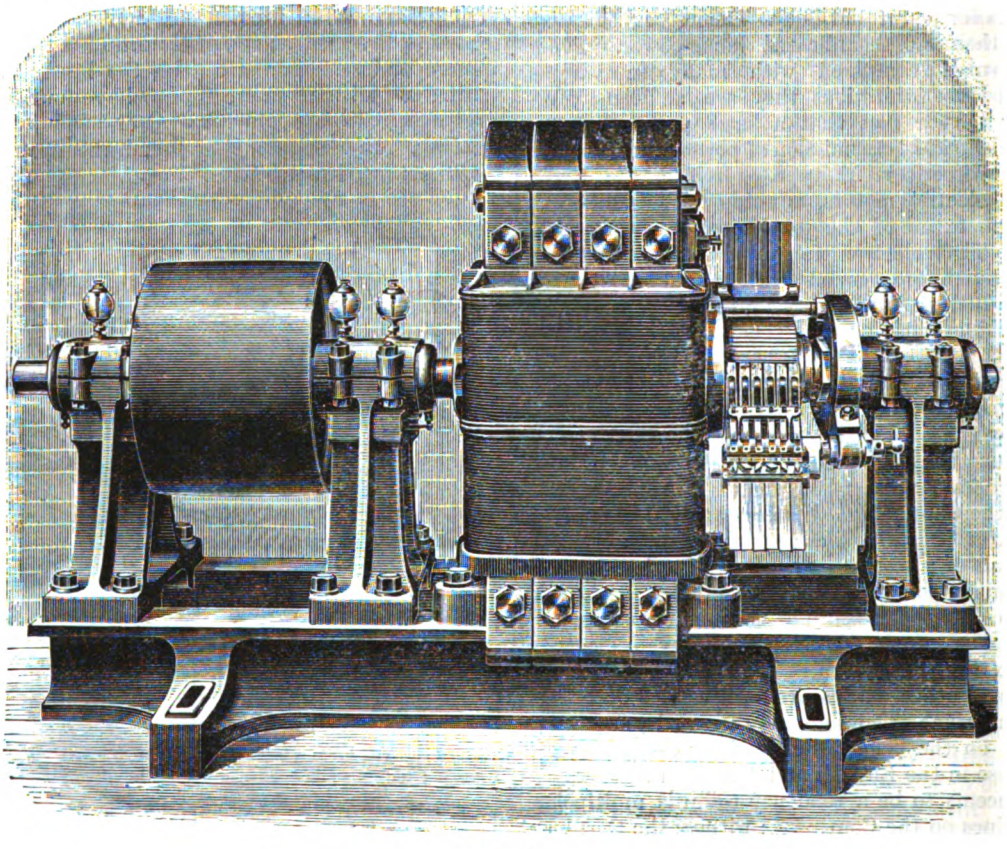

FIG. 2.

The Desrozier dynamo (Fig. 4) is an illustration of the more complicated disc armatures. It contains no iron. The method of winding the coils in two separate discs is open to criticism, and the results obtained do not seem to justify the complications involved. Though the makers claim a very large output, it seems more than probable that as good a result could be obtained with the more simple disc armature of the Thury or Edison type, whilst the difficulty of construction and of after repairs would be materially lessened.

Disc armatures for direct-current machines usually involve complications in the connections when compared with the ring or drum types. This is probably the reason why they have not come into more general use. The advantages of the disc type are undoubted for large armatures. The weight of the moving part is comparatively little, and the cooling surface is greater than that of any other design. The construction is simple if the ring winding be adopted, with a core of iron wire or ribbon. Perhaps the chief drawback lies in the balancing of the finished armature. The Henrion dynamos are of this type, being a development of the old Schuckert machine. I

* The Bradford and the Kensington Court Central Light and Power Stations have both dynamos of this type. They appear to be excellent machines.—A. T. S.

Digitized by Google

expect to hear more of machines of this type for central station dynamos of large outputs.

The Société Alsacienne have a design for dynamos of very large outputs (Fig. 5). The field-magnets are star-shaped, and are placed inside a narrow ring armature. The commutator is built on the outside of the armature windings. This design is not new. I believe Messrs. Siemens and Halske have built similar dynamos. The makers claim that this arrangement shortens the magnetic circuit. Certainly the length of the yoke is re-

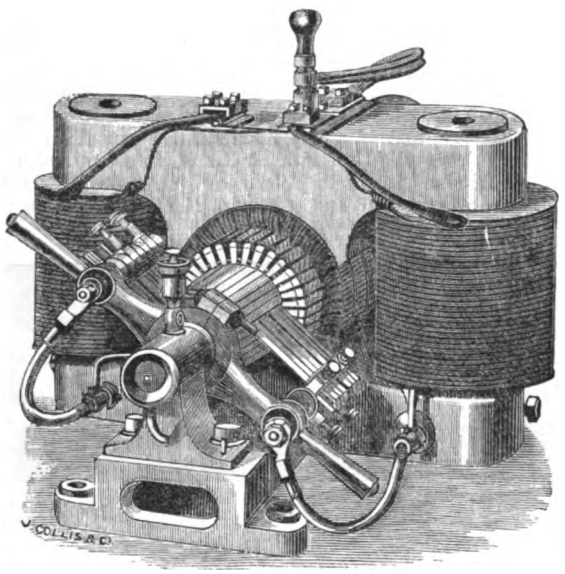

FIG. 3.

duced to a minimum, also the peripheral velocity of the conductors is a maximum for a minimum armature speed; but one would like to have more experience of the working of these dynamos before forming an opinion. The weak points in the design appear to be possibly too weak a field and certainly considerable expense in the commutator details. The construction

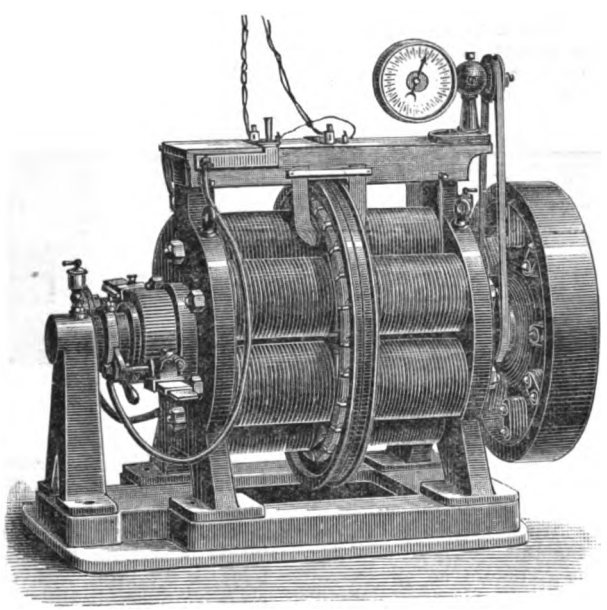

FIG. 4.

of the armature also involves apparently some difficulty. The good features that strike the casual observer are the low speed, compactness, and high weight efficiency. One of these machines running in the Galerie des Machines is coupled direct to an Armington and Sims engine of 150 horse-power. The dynamo weighs about 7 tons, and at 150 revolutions per minute gives normally an output of 1,000 amperes and 125 volts. The surface velocity of the *commutator* at this speed is about 2,800 feet per minute, so that the output can be safely considerably increased. The makers state that it will give about 1,500 amperes and 200 volts, or 300,000 watts, without undue strain or over-heating.

If the safe output be taken at 200 kilowatts, the weight per electric horse-power is approximately 58lb. At 125 kilowatts output, every 92lb. of material gives 1 electrical horse-power. I think this machine has the highest weight-efficiency of any large dynamo in the Exhibition. Allowing the same rise of temperature, a two-pole single magnet machine would certainly weigh 10 to 12 tons for a similar output; and a multipolar field, with a cylinder armature, would be scarcely less than 10 tons. Only a disc armature, with multipolar fields, could compete as regards weight. It is doubtful, however, whether this type of dynamo will come into general use. Weight efficiency is not essentially a criterion of commercial efficiency, and probably the multipolar types, with *inside armatures*, are not only cheaper, but also more reliable in practice.

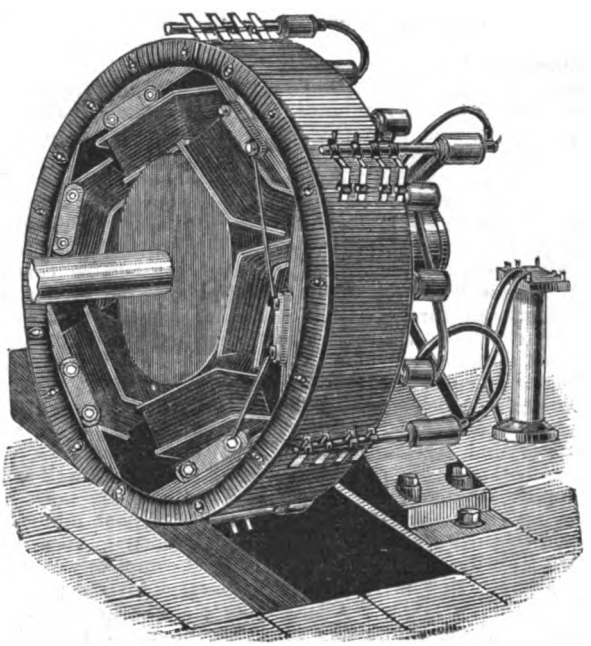

FIG. 5.

I have discussed these different types at length, in a general way, in order to emphasise the advantages of a large diameter armature, with a low magnetic density, a high peripheral speed, and a low speed of shaft. These seem to indicate the correct lines on which to design the large central station dynamos and motors which are likely to be in considerable demand in the immediate future.

(To be continued.)

ELECTRIC TRAMWAYS IN BIRMINGHAM.

The public trial of one of the storage cars to be used on the Bristol Road route took place last Wednesday. Upon drawing up in Station-street the car was immediately loaded with between forty and fifty passengers, amongst whom were the Mayor of Birmingham (Alderman R. C. Barrow), several members of the Corporation, Sir Douglas Fox, Sir Daniel Cooper, and Sir Saul Samuel, Agent-General for Australia. Besides these the number of engineers, electricians, and members of public bodies anxious to witness the trial was so great that the electric car had to be attended during its run by a large steam tramcar to carry the "overflow."

The car was not tried on the route upon which it is destined to run, but on the track where the formidable incline in Bradford-street has to be surmounted. This is about one-third of a mile long, with a gradient of 1 in 17 in one part. It was not attempted to ascend the Bradford-street hill at the same speed

Digitized by Google

as the steam-trams, the favourite device of the drivers of the latter being to "rush" it. The car, however, went steadily up without pause or hitch, and soon caught up its rival on reaching the level. Notwithstanding its momentum the car was several times pulled up in its own length on falling gradients.

By the use of automatic contact connections the accumulators can be changed in five minutes. The motor gear is fixed beneath the car on the front bogie truck, thus leaving the entrance to the car clear at either end The ease with which the car negotiated "points" and rounded sharp curves left nothing to be desired.

As the Bristol Road route is nearly free of gradients and curves, and has just been relaid with a new track, the new cars will come into operation under unusually favourable conditions.

A NEW FORM OF GAS BATTERY.

BY LUDWIG MOND AND CARL LANGER.*

In January, 1839, now over fifty years ago, Mr. (now Lord Justice) Grove published the first notice of his startling discovery—the gas battery. Since that time very little attention has been given by investigators to the subject. This is the more surprising as Grove had published a large number of experiments leading, amongst other important results, to a complete list of the voltaic relations of gases to each other and to other substances, and had pointed out in his lucid manner the great scientific interest attaching to the gas battery, which forms the simplest instrument for generating electricity, possesses remarkable constancy of E.M.F., and "exhibits such a beautiful example of the correlation of natural forces." Grove states that he never thought of the gas battery as a practical means of generating voltaic power, but, nevertheless, he indicates clearly in what directions improvements with this object should be attempted, viz., by extending as much as possible the surface of contact between the gases, the absorbent and the electrolyte. We have been engaged for several years with investigations on gas batteries, which fully corroborate Grove's view, but show that he, as well as later investigators, overlooks one important point, viz., the necessity of maintaining the condensing power of the absorbent unimpaired. We found that platinum black, the most suitable absorbent for gas batteries, loses its condensing power almost completely as soon as it gets wet, and that it is therefore necessary for our purpose to keep it comparatively dry. All attempts to attain this with various constructions of the gas battery involving the use of a liquid electrolyte failed. We have only succeeded by using an electrolyte in a quasi-solid form, viz., soaked up by a porous non-conducting material, in a similar way as has been done in the so-called dry piles and batteries.

In order to procure as large a contact as possible between the gases, the electrolyte and the absorbent, and at the same time to obtain the greatest possible duty out of a given quantity of the latter, we have adopted the following construction :—A diaphragm of a porous non-conducting substance, such as plaster of Paris, earthenware, asbestos, pasteboard, &c., is impregnated by dilute sulphuric acid or another electrolyte, and is covered on both sides with thin perforated leaf of platinum or gold and with a thin film of platinum black. The platinum or gold leaf, which serves as conductor for the generated electricity (the platinum black being a very bad conductor) is placed in contact at small intervals with strips of lead or other good conductor in order to reduce the internal resistance of the battery to a minimum. In place of the platinum or gold leaf, fine wire gauze of the same metal or of carbon may be used. The diaphragms so prepared are placed side by side or one above the other, with non-conducting frames of pasteboard, wood, india-rubber, &c., intervening, so as to form chambers through which the gases to be employed (generally hydrogen and air) are passed, so that one side of the diaphragm is exposed to the one gas and the other to the other gas, and the spaces between the diaphragms are so connected that these gases pass in contact with a number of diaphragms. Of the numerous ways in which dry gas batteries can be constructed we will describe two. One of these constructions, suitable for laboratory work, shown in Fig. 1, consists of an earthenware plate, M, impregnated with sulphuric acid and cemented into an ebonite frame, R. At a short distance from and all around the plate a copper wire, A, is let into the ebonite frame. The earthenware plate is covered with platinum leaf, which has been perforated with a very large number (1,500 per square cm.) of small holes, and which extends over and is in metallic contact with the copper wire. To protect the latter from corrosion, and to avoid local action, molten paraffin is put over the platinum leaf where it is in contact with the copper wire. Where the platinum leaf is in contact with the earthenware plate it is coated by means of a brush with a very thin film of platinum black, which penetrates through the pores and holes of the platinum leaf, and thus comes into contact with the electrolyte. The frame R is fixed by means of screws between the two ebonite plates, E, E', with two india-rubber frames, K, K', intervening, thus forming two gas-tight chambers, G, G', through which the gases to be used are let by the tubes O, O' and H, H'. The second construction, Fig. 2, consists of a number of elements, each of which is composed of two frames of lead and antimony, consisting of a broad edge, R, conducting strips, A, and flaps, F, with holes and channels, O. H, which form the inlets and outlets for the gases. These frames are coated with an insulating layer, a, of a mixture of gutta-percha, beeswax, resin, and paraffin. Between the two frames we insert a thin sheet, S, prepared by coating a piece of cloth with plaster of Paris, and made impervious round the edges by the same insulating mixture, and then the open spaces formed by the conducting strips A are filled up with plaster of Paris, mixed up with dilute sulphuric acid, so as to obtain an even plate. This is now coated with platinum leaf and platinum black in the same way as

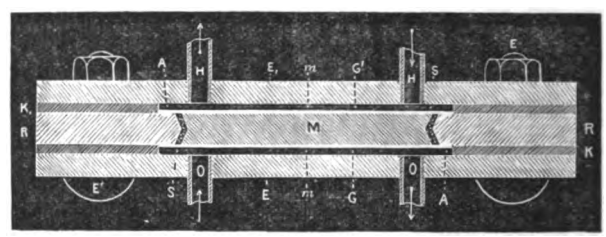

FIG. 1

before described. A number of these elements are put side by side, or one above the other, with non-conducting frames, K, of pasteboard intervening, so as to form gas chambers, G_1, G_2, G_3, which are connected by means of cork or rubber washers, Q, so that the gases admitted by the pipes O pass through the whole series of chambers. The first and the last gas chamber are formed by an additional pasteboard frame intervening between the last plates and two plates of zinc, Z_1, Z_2, extending beyond the battery plates, which hold the set together. The whole set of plates is now coated on the four sides not covered by the zinc plates with a mixture of beeswax and resin, so as to obtain a block which is perfectly gas-tight all round, and the space V left between the two zinc plates is then filled up with plaster of Paris, so as to obtain one solid compact block with no openings except the entrances and exits for the gases. This is closed by four more zinc plates, Z_3, Z_4, Z_5, Z_6, which are soldered together so as to form a box.

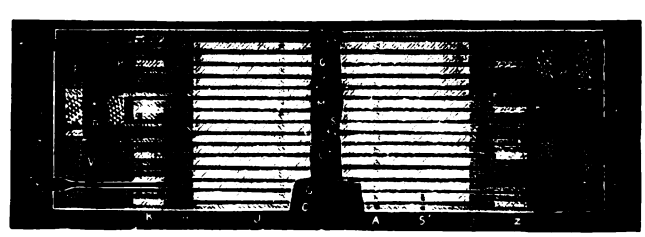

FIG. 2

The E.M.F. of this battery we found to vary considerably, according to the way in which the platinum black is prepared. The best and most regular results we have obtained from platinum black made by neutralising a boiling solution of $PtCl_4$ with Na_2CO_3, and adding this slowly to a boiling solution of sodium formiate. With this we obtain an electromotive force of 0·97 volt with the open circuit. The internal resistance varies considerably with the thickness of the porous plates, the amount of the electrolyte contained in these, and the surface of these plates. Plates of gypsum of 8 mm. thickness and 350 cm. surface gave an internal resistance of 0·02 ohm.

The current obtainable from these batteries varies necessarily with the external resistance. It is possible to obtain eight amperes from one such element, but the E.M.F. of the battery sinks at a very much more rapid rate than with constant batteries if a strong current is taken out, and the work done by the battery is not, as in constant batteries, at its maximum when the internal and external resistance are equal. Thus we found with a small battery of 42 sq. cm. surface and 0·36 ohm internal resistance the following results :—

R. Internal resistance in ohms; R_1. External resistance in ohms; P, Difference of potential at the poles; S. Strength of current in amperes; E. E.M.F. in volts, determined by the first deflection of the galvanometer needle one second after opening the circuit; E_1. Calculated E.M.F. in volts; D. Difference of E and E_1 = increase of E.M.F. during one second, showing rapidity of absorption of the gases with varying saturation of the platinum; A. Work done by the battery in watts.

These figures show that in the case of the battery experimented with the maximum of work was obtained with an external resistance of about double the internal resistance. This result is probably due, as pointed out by Dr. C. A. Wright,* to the fact established by Favre† and Berthelot,‡ that the gases occluded or condensed by platinum black evolve less and less heat per unit weight of gas the more gas the platinum black had previously condensed. The heat evolved by the condensation of the gases by the platinum black, or a certain portion of this heat, is in all probability lost for the production of the current; it follows that the more the platinum black is saturated the less energy will be lost by the condensation of the gases, and *vice versa*. Now, probably the rate of absorption of gas by the platinum black will rapidly diminish as it is more and more saturated with gas, so that in order to maintain it saturated or nearly saturated only a moderate amount of current can be obtained from a given surface, while if it is kept far below the saturating point it will condense the gases very rapidly, and a very large current can consequently be obtained.

As a practical limit we prefer to work the battery with an E.M.F. with closed circuit of about 0·73 volt. This allows us to take from 2 to 2½ amperes (1·45—1·82 watt) out of an element with an active surface of 700 sq. cm., covered with 0·35 gr. of Pt leaf and 1 gr. of Pt black, which gives a useful effect of very nearly 50 per cent. of the total energy contained in the hydrogen absorbed in the battery. We have found practically no difference in these results, whether we were using O and H or air and gases containing 30 per cent. to 40 per cent. of H, such as can be obtained by the action of steam or air and steam on anthracite, coke, or coal. With a useful effect of 50 per cent., one-half of the heat produced by the combination of the H with the O is set free in the battery, and raises its temperature. By passing through the battery a sufficient excess of air, we can keep the temperature of the battery constant at about 40° C., and at the same time carry off the whole of the water formed in the battery by means of the gases issuing from it, so that the platinum black is kept sufficiently dry, and the porous plate in nearly the same state of humidity.

The E.M.F. of the open battery is very considerably below what it should be according to Thomson's theorem. The combustion of H and O should produce an E.M.F. of 1·47 volts, while we only obtain 0·97. It does not seem to us probable that this difference can be explained in the same way as the deviations from this theorem in a number of abnormal voltaic batteries have lately been explained by Chroustchoff and Sitnikoff,§ viz., by the Peltier effect, which would probably not be different for the combinations HPt,SO_4H_2 and SO_4H_2,PtO; nor do the causes by which Herroun‖ explains this deviation appear to us to be applicable to the gas battery. It seems more probable—and what we have stated above respecting the rapid loss of the E.M.F. when taking out larger currents favours this view—that this loss of energy is to some extent due to the heat given out in the condensation of the gases by the platinum black.

In the hope of throwing some light upon the question of the disappearance of energy in the gas battery, we determined the E.M.F. of various combinations by means of a block of plaster of Paris impregnated with sulphuric acid, one end of which was covered with platinum foil and platinum black, and arranged so that it could be exposed to H or O, while the other end was plunged into a beaker which contained the liquid electrolyte and the electrode which we wished to examine. The results show that the loss of energy is very nearly the same per equivalent of O consumed, when PtO is used as the negative electrode, whether PtH, zinc, cadmium, or copper is used as positive electrode, and also that PtH with copper in copper sulphate, or carbon in nitric acid, as negative electrodes, gives nearly the theoretical E.M.F. It would thus seem as if the loss of energy in the gas battery occurred on the PtO electrode; but the question is undoubtedly a complicated one, and requires further study before an explanation of it can be attempted.

This battery differs from all other gas batteries in showing all the characteristics of polarisation after it has been at work for some length of time. It loses within an hour from 4 to 10 per cent. of its E.M.F. As the chemical processes taking place at the electrodes could not explain this, we had to look out for its cause in another direction, and found it to be the transport of the sulphuric acid from the O to the H electrode, resulting in the acid becoming gradually more concentrated on the positive side and weaker on the other, which we have established by analysing the gypsum scraped off below the platinum leaf at both sides. Probably this difference of concentration of the acid sets up a counter-current. In order to counteract this disturbing influence and to keep the current constant, we interchange the gases in the battery from time to time—say once an hour—so that the current goes in an opposite way through the porous diaphragm, and transports the sulphuric acid back. This necessitates, where constant currents are wanted for a longer period, the working of a number of elements or batteries connected by means of a commutator in such a way that one element or battery will always be out of the circuit, and have its gases changed, and be replaced in the circuit at the moment when the next element or battery is switched out for the same purpose.

In using, in place of sulphuric acid, a solution of sodium chloride as electrolyte, we found, after working the battery for some time, sodium hydrate on one side and HCl on the other side of the battery, and have been able to determine in this case the polarisation to be equal to 0·54 volt, which very nearly accounts for the difference between the E.M.F. of the open battery and the E.M.F. calculated according to Thomson's theorem. The E.M.F. of PtH,NaClAq,PtO we found equal 0·86 volt, which, added to the polarisation of 0·54 volt just mentioned, gives a total of 1·40 against the theoretical figure for H, O = 1·47. By changing the gases after the polarisation was fully established, the battery showed an E.M.F. of 1·39 volts. This observation, as well as the determinations of Peirce,* of the E.M.F. of gas batteries with the same gases and different electrolytes, shows that the electrolyte also has considerable influence upon the E.M.F.

We hope by further investigation to arrive at assigning their proper value to the various causes affecting the E.M.F. of gas batteries.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, November 1st.

PHYSICAL SOCIETY.

5 p.m. "On Electrifications due to the Contact of Gases with Liquids." By J. ENRIGHT. "On a New Electric Radiation Meter." By W. G. GREGORY, M.A. "On a Physical Basis for the Theory of Errors." By C. V. BURTON, D.Sc.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at the St. James's Hall Restaurant.

MONDAY, November 4th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Paper to be read, "Modern Gas Engine Practice." By SAMUEL GRIFFIN.

INSTITUTION OF ELECTRICAL ENGINEERS.

7:30 p.m. Dinner at the Criterion Restaurant, Piccadilly.

TUESDAY, November 5th.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture "Dust." By A. P. LAURIE.

THURSDAY, November 7th.

CHEMICAL SOCIETY.

8 p.m. Papers to be read: "The Isolation of a New Hydrate of Sulphuric Acid existing in Solution." By S. U. PICKERING. "Further Observations on the Magnetic Rotation of Nitric Acid, of Hydrogen Chloride, Bromide, and Iodide in Solution. By Dr. W. H. PERKINS, F.R.S. "On Phosphoryl Trifluoride." By T. E. THORPE, F.R.S., and F. T. HAMBLY. "On the Acetylation of Cellulose." By C. F. CROSS and E. BEVAN. "On the Action of Light on Moist Oxygen." By A. RICHARDSON. "Anhydracetophenone Benzil and the Constitution of Linius Lepidens." By Drs. JAPP, F.R.S., and KLINGEMAN.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, **1,** *Salisbury-court, Fleet-street, London, E.C.*

ELECTRICITY IN MINES.

It is a somewhat remarkable fact that Great Britain, with her output of over 150,000,000 tons of coal per annum, has as yet availed itself only to a very limited extent of the enormous advantages resulting from electric lighting and transmission of power in mines. No doubt a good many mines, especially in Wales, are lighted by fixed glow lamps, and the number of portable electric miners' lamps in use in our pits is steadily increasing; but in comparison with the enormous field for its application, the total of electric lighting done in mines is still insignificant, and as regards transmission of power the case is yet more unfavourable. A few pumping and hauling plants, and a few coal-getting machines, is all we have to boast of; but these few machines and plants do their work so satisfactorily that duplicate orders almost invariably follow. Those few mine-owners and managers who have tried electric-power transmission want more and more of it, and are discarding their old plant for the new system with perfect confidence. But why have so few tried it, and why do not more follow the example set them by their enterprising neighbours? We fear that in this respect both the electrical and the mining engineers are to blame. The former, as a rule, know nothing of mining and its requirements, whilst the latter know about as much of electricity and its capabilities. The general run of mining engineer is a rule-of-thumb man, accustomed to rough and heavy work, and

Digitized by Google

not given to bother his head much about elegance of design, perfect workmanship, or high efficiency of the machinery he employs. Coal is cheap at the pit's mouth, and as long as his hauling gear, pumps, and other machinery can be kept going somehow without a break-down, he is satisfied to let things remain as they are. The electrical engineer has thus no easy task in persuading him, first, that the plant which he has been in the habit of using for generations is capable of improvement; and next, that electricity is the agent which alone renders this improvement possible. This difficulty is all the greater because the average electrical engineer is too much of an electrician, and too little of an engineer; to say nothing of his total ignorance of mining work. Before we can hope to see our coal mines become a profitable field for the employment of electric power transmission, both the mining and the electrical engineer must pass through a course of education—not such a course as is provided in our technical colleges, but such a one as actual practice and the close study of what has already been done in that direction alone affords.

Viewed in this light, the lecture which Mr. ALBION T. SNELL recently delivered in the Mining School at Wigan, and of which we printed an abstract in our last issue, is of considerable importance. In this lecture Mr. SNELL brought before his audience a plain statement of what had been done with electric power transmission in some of the hauling and pumping plants with which he had been connected. In one case, that of the Normanton plant, comparative tests were made between pneumatic and electric transmission of power, and the results will come as a startling revelation to those who, influenced by Prof. KENNEDY'S able Paper on the Paris Compressed Air-Power Supply, read before the last meeting of the British Association, were beginning to again lean towards a system of transmitting power which has over and over again been proved to be uneconomical. Mr. SNELL did not speak as if he held a brief for electric transmission, but simply stated facts, allowing them to speak for themselves. Had he chosen he might have made out a very much stronger case against pneumatic and for electric transmission than he actually did. He might have pointed out that the difference in efficiency (12 to 14 per cent. with pneumatic, against 43 to 44 per cent. with electric transmission) was, as far as the coal bill went, really the least important part of the comparison; that the importance lay in the necessity of putting up a boiler and engine about three times as large to do the same work; that the cost of the compressors and motors considerably exceeded that of dynamos and motors; that the cost of attendance was also greater; and last, but not least, that the cost and trouble of keeping in order the air pipes in workings which are continually shifting, was many times greater than the corresponding items when a cable is used. Our electrical readers will, perhaps, be astonished to learn that in many cases the air main must be provided at every twelve feet or so with a ball-and-socket joint, or other flexible connection, and that where the distance is at all considerable the capital outlay for this air main alone exceeds that for dynamos, leads, and motors. The comparatively high efficiency which Prof. KENNEDY obtained in his experiments at Paris, where the air motor which he tested was in the same building with the air compressors, and where, consequently, losses by leakage were excluded, is, for this, and another reason to which we shall presently refer, quite unattainable in mining work. To keep the flexible air main absolutely tight is obviously impossible, and a loss of power by leakage is, therefore, a necessary evil. Whether the Paris air mains are tight is a question which need not concern us here, but it is certain that the motors considered by themselves must have a higher efficiency than air motors employed in a colliery. The reason is simply this, that above ground the power given out by the motor is considerably increased by heating the air before it enters the motor. The energy thus communicated to the motor in the shape of heat is credited to the whole system of transmission, and hence the efficiency becomes greater than it would otherwise be. If this principle be carried to its greatest extent the air becomes simply a convenient medium for the transformation of heat locally applied into mechanical energy; but this is not transmission of energy to a distance, it is conversion of one form of energy into another form on the spot. In a mine the application of heat to the air motor is clearly inadmissible, and hence the much lower efficiency as compared with air motors above ground. We have dwelt on this aspect of the case at some length to prevent any possibility of an unfair comparison between the results of Professor KENNEDY'S experiments and the figures given by Mr. SNELL. It might otherwise have been objected that the air motor tested at the Normanton Colliery was of bad design, and that this was the only reason why there the efficiency came out at 14 per cent., whereas in the Paris plant it came out at something approaching 40 per cent. Whether the motor was or was not inferior we do not pretend to say; this much is certain, that it could not have been so much inferior as to account for the whole of the difference in the efficiency, and that even were the motor as perfect as good workmanship and mechanical skill can make it, the efficiency of the whole air-power plant can never even approach that which is easily obtainable with an electrical plant.

Apart, however, from questions of first cost and efficiency, the electric power transmission has many other advantages. In describing the Llanerch Colliery Hauling and Pumping Plant, Mr. SNELL drew attention to the fact that the hauling power is under perfect control, and the trams can be moved a few inches at a time or hauled up the incline at full speed with equal certainty. Not only is the power under almost instantaneous control, but the engineman knows at any moment how much power his dynamo is giving off. He need only watch the ammeter to tell at a glance the number of trams on the rope, and if a derailment should take place or the progress of the trams be impeded by any obstacle, the needle of the ammeter will show this immediately, giving the engineman warning to switch off before any mischief is done. With compressed air power, this would obviously be impossible. The amount of attendance required underground is very trifling. In the Linlithgow Pumping Plant, for instance, the electro-motor and pumps are visited once a day by an attendant, who has simply to fill up the lubricators and may then leave the machinery to take care of itself. It need hardly be said that such admirable results are only possible with apparatus constructed in a very substantial manner. It is not to be expected that enginemen in a colliery will treat dynamos and motors with the gentleness and care generally bestowed on scientific apparatus. They are used to rough, heavy machinery, which will stand a good deal of ill-treatment, and the secret of success lies not in trying to educate men up to the level of professors, but to make the machinery strong enough, so that the men may deal with it in the rough manner to which they are accustomed. The other day we saw some electric coal-cutting machines, and complimented the maker on the very substantial design. "Yes," he said, "we are obliged to make our machines so strong that the men, if they be so minded, might adjust them with a sledge-hammer without doing any damage." In this sentence lies the secret of success. Let the electrical engineer design his machinery strong enough for the roughest usage, and the mining engineer will be ready enough to adopt it.

OBITUARY.

M. LOUIS CURCHOD.

It is with great regret that we announce the death of M. Louis Curchod, Director of the International Telegraph Bureau, who died at Berne on the 18th October, after a long illness.

Born at Crissier (Switzerland) on the 7th October, 1826, M. Curchod completed his studies at the École Centrale des Arts et Manufactures de Paris, which he left in 1849 with the diploma of engineer. From that time he devoted himself to telegraphy, and soon accepted the post of Inspector in the Federal Telegraphic Service. His brilliant intelligence, his eagerness for work, and his technical knowledge soon brought him to the notice of the Conseil Fédéral, and he was appointed Director of the Swiss Telegraph Service. It was in this quality that he took part in the preparation of the first International Telegraph Conventions, which were entered into at first with the adjoining countries, and afterwards with most other European States. Charged with representing his country at the International Telegraph Conference held in Paris in 1865, he brought to bear the experience which he had acquired in organising the Swiss Telegraphs, and he rendered great assistance at this first meeting of the heads of the telegraphic system of Europe, among whom he immediately took the influential position he occupied until his death. The International Conference held in Vienna in 1868 gave him a fresh opportunity of displaying his remarkable administrative qualities. The formation of the International Telegraph Bureau, the management of which was confided to the Swiss Government, was one of the results of this Conference, and M. Curchod, who had taken great part in the creation of this new institution, was naturally the man to be appointed to the direction of it. To this office, from which he did not separate himself except for a short time when he filled the post of Managing Director of the Société du Câble Transatlantique Français, M. Curchod devoted all his time and all his energy. He took part in the work of the Telegraph Conferences of Rome (1871), of St. Petersburg (1875), of London (1879), and of Berlin (1885), and he contributed greatly to the work realised by these various Conferences, fulfilling with great distinction the *rôle* of adviser and conciliator whenever questions arose upon which opinions were divided. M. Curchod of course received numerous testimonies of the high esteem in which he was held by the Governments belonging to the Telegraph Union. He was Grand Officer of the Order of St. Stanislas, Commander of the Order of the Royal Crown of Prussia, Officer of the Legion of Honour, Commander of the Order of the Royal Crown of Italy, Grand Officer of the Order of Francis Joseph, &c., &c.

The void which M. Curchod's premature death has made at the International Telegraph Bureau will be difficult to fill.

THE PROPOSED NATIONAL MEMORIAL TO DR. JOULE.

The following letter from Sir Henry Roscoe appeared in *The Times* of Saturday:—

SIR: The scientific and also, I believe, the general public will learn with satisfaction through your columns that at the meeting of the Council of the Royal Society held yesterday, at which the lamented death of our illustrious Fellow was formally announced, it was unanimously resolved, on a motion proposed by myself, to appoint a committee to consider, and, if the proposal be accepted, to carry out, the erection of a national memorial to the late Dr. Joule.

The committee is one truly representative of British science. It consists of the presidents and officers of the Royal Society, and of several members of the Council and other Fellows. To these will be added, for of their consent and co-operation there can be no doubt, the presidents of many of the scientific societies and associations, as well as other influential representatives of those sciences to which the labours of Joule have added such lustre.

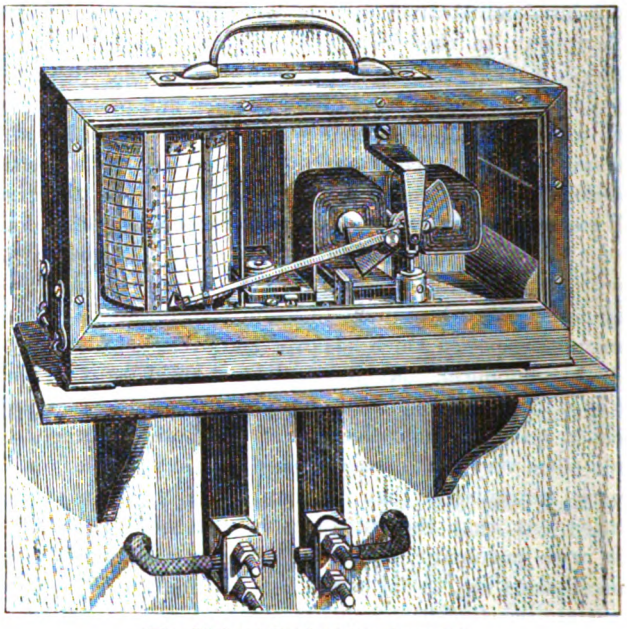
It is only proper that the Royal Society, representing as it does British science at once in its highest and widest forms, should take the initiative in promoting the national recognition of one whose services to science and to mankind are conceded by all scientific men to be only second to those rendered by Newton himself.

I am, your obedient servant,

October 25. HENRY E. ROSCOE.

THE RICHARD REGISTERING CENTRAL STATION INSTRUMENTS.

Amongst the fine show of instruments of precision exhibited at the Paris Exhibition by MM. Richard Frères are some useful registering ammeters and voltmeters, specially designed for central station purposes These instruments (*see* Figure) consist of a horse-shoe electro-magnet with an iron armature, in appearance not at all unlike a ship's propeller, which moves in close proximity to the poles, round an axis parallel to the two limbs of the magnet. The resistance of the magnetic circuit varies, therefore, considerably, according to the position of the armature, and is at a maximum when the pointer is at zero. The couple which acts on the armature when the instrument is in circuit is opposed by a weight hung at the end of a small lever. The instrument shown in the figure is an ammeter capable of measuring currents up to 100 amperes. By means of a long pointer a considerable amplification of the movements of the armature is obtained. To the end of this pointer a pencil is attached, and the value of the current at any moment is marked on the revolving drum, which is divided in the manner shown, and which turns at any desired speed. The



The Richard Registering Ammeter.

vertical graduated scale enables one to read off the current in the usual way whenever requisite. In some instruments the drum is replaced by an endless strip of paper unwound at the rate of three centimetres per minute. The ammeters absorb from 6 to 120 watts, according to their size (10 to 2,000 amperes). The voltmeters, which measure up to 120 volts, have 1,500 ohms resistance, and absorb 96 watts, they carry 2·5 kilogrammes of wire, and never heat to more than 8°C. about the surrounding atmosphere. These ammeters and voltmeters have been found to act as very efficient checks upon the watchfulness of central station attendants. It is possible also to use the current records as electricity meters, by simply cutting out the curve and weighing the lower portion of the paper.

NOTE ON THE EMPLOYMENT OF CHROMIC ACID INSTEAD OF NITRIC ACID IN THE BUNSEN CELL.*

BY J. WILSON SWAN, M.A.

Thanks to the initiative of Mr. William Rowell, of Newcastle, chromic acid is manufactured on a much larger scale than formerly, and its price is so reduced as to bring it into competition with the chromates of the alkalis, and with nitric acid as the depolarising agent in the Grove and the Bunsen cell.

* Paper read before the British Association in Section "A," Newcastle-on-Tyne, September, 1889.

Digitized by Google

Ever since these cells were first used, a way of escape from the necessity of employing nitric acid has been continually sought, and, it must be admitted, with small success.

Where it was required to produce a large current for a short time, the Bunsen cell charged with a strongly acid solution of bichromate of potash instead of nitric acid has been used with good effect, but where a large current was required to be steadily maintained during several hours this substitution has proved to be wholly inefficient.

When, for example, the resistance of the cell so charged and the external resistance are about equal, it is very well known that there is an almost immediate and very large decrease of current. When chromic acid became an article of commerce at a moderate price, it seemed to me worth while to try afresh what could be done with it. Out of a great number of experiments (in which I have been assisted by Mr. Leigh Powell), I propose to bring before you the results of two, with a view to show, comparatively, the discharge of a Bunsen cell charged in the usual manner, and a discharge of the same cell similarly charged as regards the zinc compartment, but with a chromic acid mixture instead of nitric acid in the carbon compartment. The cell employed was of the Holmes Burke construction ; it consisted of two carbon and two zinc plates, a porous inner cell, and a vitreous earthenware outer cell. The carbon plates were in the porous cell, and the zinc plates outside it. The size of the plates was 9½in. by 7in., and as the two carbon plates were not far apart, only their outer surfaces would take any large part in the action of the battery.

To take advantage of the lower resistance of the cell at a high temperature, the heat generated by mixing the water and sulphuric acid was utilised. The discharge was commenced while the liquid was hot, and the cell was closely surrounded by a wall of sawdust three inches thick. Under these conditions the temperature was maintained during the whole time (13 hours) at between 90deg. and 120deg. F. The resistance external to the cell was adjusted to a quantity which was intended to be and which proved to be nearly the mean resistance of the cell itself during the time of discharge, and, therefore, the electromotive force available for external work was nearly one volt.

The diagram shows the curve in amperes of two discharges. The black line gives the curve of the discharge when the cell was used as a Bunsen, *i.e.*, with nitric acid in the porous cell, and the red line shows the discharge of the same cell with a mixture of chromic, sulphuric, and nitric acids substituted for the nitric acid. The composition of this solution was as follows :—

	Parts by Weight.
Nitric acid specific gravity 142	1
Chromic acid	3
Sulphuric acid	6
Water	5

It will be observed that the proportion of nitric acid in the mixture is very small. With this mixture there is no fuming such as occurs during the nitric acid discharge. It was found impossible to get the effect required without *some* nitric acid, but with this small proportion added to the large proportions of sulphuric and chromic acids, a depolarising effect was obtained practically equal to nitric acid. Several circumstances attending discharge with the chromic acid mixture suggests that the nitric acid in it, small as the quantity is, plays a chief part in the electrolytic action, and it is certain that without it a very inferior result is obtained.

The zinc compartment, in both experiments, contained three-fourths of a gallon of sulphuric acid and water of specific gravity 117deg.

The carbon compartment,

In the nitric acid experiment contained :—	In the chromic acid experiments contained :—
Three-eighth of a gallon of nitric acid, specific gravity 136.	Three-eighth of a gallon of the chromic mixture.

The diagram which was exhibited in connection with this Paper showed broadly that the chromic acid mixture was equal to nitric acid, with a large discharge extending over a long time. During 13 hours there was a drop in the current from 20 amperes at the beginning to 18 amperes at the end of the discharge. The chromic acid mixture in the carbon compartment, and also the dilute sulphuric acid in the zinc compartment, were both nearly exhausted in that time ; but in the case of the nitric acid discharge there was still a considerable further effect obtainable by renewal of the dilute sulphuric acid. The quantity of the nitric acid might, therefore, have been reduced without reducing the duration or quantity of the discharge.

In attempting to reduce the proportion of nitric acid in the chromic acid mixture to the smallest efficient amount, it was observed that there was a difference in the proportion required for carbon and for platinum, much more nitric acid being required to produce the kind of electrolytic action which sustained a large current, and in which there was at first and during a very considerable period of the discharge an entire absence of effervescence at the surface of the negative element, and towards the end a slight emission of nitrogen dioxide. With the chromic acid mixture employed in the discharge, described in the diagram, there was no emission of gas at the surface of the negative element when carbon was used, but when platinum was substituted for carbon there was an immediate and copious emission of hydrogen at the surface of the platinum, and a large fall in the current.

It has been observed that occasionally the carbon electrode exists in a peculiar physical condition when it has to remain on circuit for, sometimes, a very considerable time before the current rises to its normal and steady state ; but this active condition may be at once arrived at by moistening the carbon with nitric acid before introducing it into the chromic acid mixture.

FIFTH REPORT OF THE COMMITTEE APPOINTED FOR THE PURPOSE OF CONSIDERING THE BEST MEANS OF COMPARING AND REDUCING MAGNETIC OBSERVATIONS.*

The Committee are able to report the establishment of regular magnetic observatories, where continuous photographic records of the magnetic elements are taken, at the United States Naval Observatory at Washington, and also at Los Angelos in California. The instruments used are of the Kew pattern, with the same time-scale, and the scale-coefficients for horizontal and vertical force instruments at Washington are very nearly those recommended by the Committee in their Third Report (1887), and which are in very near agreement with those at Vienna, St. Petersburg, and some other observatories.

The Committee report, further, that the plan proposed by them in their Third Report for the Comparison and Reduction of Magnetic Observations has been adopted at the United States Naval Observatory at Washington, which is now prepared to take part in the general scheme of co-operation proposed by the Committee. Copies of the photographic registers of the three elements for April 21st to 30th, May 1st to 31st, and for June 1st to 30th have been forwarded to the Committee from Washington, with tables of scale and temperature coefficients. There are also forwarded two prints showing the reduction of the declination for the year 1888, by means of a graphic composite curve, made by tracing over one another with a pantograph the daily curves of the month, and then drawing a curve through them to show the monthly means.

There are also forwarded from Washington a set of prints showing the comparison of the disturbances of declination and horizontal force at Washington for 99 days of 1888, and another set of prints showing the comparison of disturbances of declination on certain selected days at Washington, Los Angelos, and Toronto, all reduced to the same time-scale of 30·6 millimetres for two hours, *i.e.*, the time-scale of instruments of the Kew pattern.

Days in 1888 selected by United States Naval Observatory for comparison of magnetic disturbances of Declination and Horizontal Force.

January	7, 14, 15, 23, 24, 27.
February	10, 11, 18, 19, 20, 21.
March	7, 8, 9, 10, 15, 16, 17, 18.
April	2, 3, 4, 5, 10, 11, 12, 13, 14, 30.
May	1, 6, 7, 8, 9, 10, 11, 20, 26.
June	2, 3, 4, 5, 6, 21, 22, 23, 24.
July	1, 2, 7, 8, 16, 19, 20, 21, 22, 27, 28.
August	2, 3, 15, 16, 17, 18, 19, 30.
September	7, 8, 11, 12, 13, 14, 15, 19, 25, 26, 27.
October	5, 11, 19, 20, 30, 31.
November	3, 4, 6, 16, 17, 18.
December	5, 7, 13, 14, 23, 24.

The Committee are more than ever of the opinion expressed in their Third Report, "that the establishment of regular magnetic observatories at the Cape of Good Hope and in South America would materially contribute to our knowledge of terrestrial magnetism."

The Committee consider that it would be desirable to publish annually in a collected form for certain selected days the curves of the three magnetic elements, *i.e.*, declination, horizontal force, and vertical force, taken at the different English and Colonial magnetic observatories, choosing for selection in 1888 the days for which the curves are published in the "Greenwich Observations."

* British Association, Section A, Newcastle-on-Tyne, September, 1889. The Committee consisted of Prof. W. Grylls Adams (Secretary), Mr. W. Lant Carpenter, Mr. C. H. Carpmael, Mr. W. H. M. Christie (Astronomer Royal), Prof. G. Chrystal, Capt. Creak, Prof. G. H. Darwin, Mr. William Ellis, Sir J. H. Lefroy, Prof. S. J. Perry, Prof. Schuster, Prof. Sir W. Thomson, and Mr. G. M. Whipple.

THE CHOICE OF CABLES FOR ALTERNATING CURRENTS.*

BY CH. JACQUIN.

Electricians have long discussed, and are still discussing, the description of cable to be used for alternating currents. When alternating currents were utilised for the first time, *i. e.*, for supplying the Jablochkoff candles, ordinary cables were employed. Since then, owing to the introduction of the transformer system, the use of alternating currents has largely increased, and numerous mains for alternate-current distribution have been laid. Some theorists then expressed the opinion that instead of employing two separate conductors, one going out and the other returning, it would be far preferable to have a single concentric cable, the central core forming one of the conductors, and the other consisting of a ring insulated from the core. In such a cable the two conductors are at each moment traversed by opposite currents, and consequently give rise to no field of force outside the conductors. Thus these cables produce no induction troubles on telephone lines. Moreover, the metallic sheathing is not the seat of any parasitic current. A simple cable, on the contrary, produces a variable circular magnetic field, and if it is covered with a metallic sheathing, we have a loss of energy due to the Foucault currents and other induction phenomena in this sheathing. Many, believing these losses to be excessive, have thought that armoured cables should for this reason be concentric. If it is true that concentric cables save us from induction, they offer in other respects serious inconveniences. The central stations at Berlin and elsewhere soon found this out. Defective insulation between the core and the annular ring gave rise to serious accidents. The cause of these accidents is easily understood. In a concentric cable the difference of potential between the two conductors is double that which exists between the core of a simple cable and the earth The insulation between the two conductors of the concentric cable should therefore have at

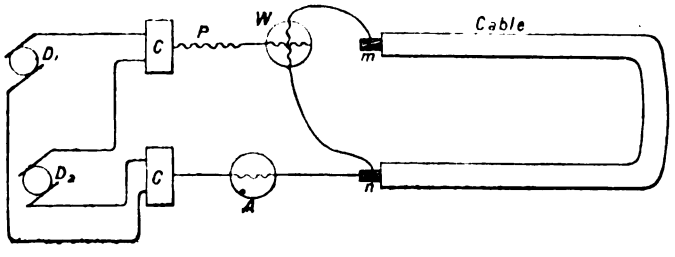

FIG. 1.

least twice the value of that of a simple cable. Now, in the first concentric cables, the insulation was far from being equal to that of the simple cables, for the makers, in the manufacture of them, had employed as a dielectric merely textile fabrics impregnated with pitchy substances. If we wish to have concentric cables sufficiently insulated, we must use very thick layers of gutta-percha, which are very difficult to vulcanise at their periphery, and then the cables become very expensive. Thus the concentric cables for the Municipal Central Station at the Halles Centrales cost 33fr. per metre, whereas the corresponding simple cable costs 8·35fr. Thus the cost per metre (lead and return) amounts in the case of the concentric cable to 33fr., against 16·7fr. for the ordinary cable. In other words, it costs twice as much. In the face of these figures it may be asked whether it would not be better to return to the simple cable. In order to answer this question it is necessary to ascertain whether the loss of energy which takes place in a simple armoured cable is really so great as to necessitate the employment of concentric cables. The question being too complex to allow of any figures being fixed *à priori*, it was found necessary to solve it by direct experiment. It was for this purpose that I carried out the following experiments. It is not surprising that no experiments of the kind had previously been made; as a considerable amount of expensive material and apparatus is required, all of which M. Henri Menier placed at my disposal in his works at Grenelle.

The plan of my dispositions is shown in Fig 1. A cable of 200 metres, unwound upon the ground, may be traversed either by the alternating currents from the dynamo D_1, or by the continuous currents from the dynamo D_2, by means of the commutator C. In the circuit are placed a rheostat, P, an electro-dynamometer, A, and the fixed bobbin of a wattmeter, W. The movable bobbin of this latter is connected with the terminals *m*, *n* of the conductor.

An alternating current from D_1 is first sent through the cable. If the cable is armoured, hysteresis, induction currents, and Foucault currents are produced in the sheathing, having the effect of creating a counter-electromotive force in the conductor; so that in order to obtain an effective current in this conductor, it would be necessary to have at the terminals of the cable a difference of potential above that given by Ohm's law. The deviation a of the wattmeter will then give the total power P expended on the cable for an effective current given by the electro-dynamometer A. Substitute for the dynamo D_1 the continuous-current dynamo D_2, and bring the electro-dynamometer to the same deflection, a smaller deflection, a', is read. The current being continuous, there is no induction in the sheathing; the wattmeter then measures simply the power $C^2 R$ expended in the conductor. The power p dissipated in the sheathing is determined by the two experiments

$$p = P - C^2 R.$$

But what is especially interesting is not the absolute value of the power dissipated, but the ratio

$$\frac{p}{C^2 R} = \frac{a}{a'} - 1,$$

which depends only on the ratio of the deflections of the wattmeter.

These are the results obtained with an alternating current of 3,000 periods per minute. If we pass an alternating current through a cable without a sheathing, wound upon the iron bobbin which serves to transport it, the power dissipated in this bobbin is equal to ten times the power expended in the conductor. This shows of what importance the parasitic currents are when the mass of iron is not divided. Once unwound, the cable without sheathing expends no more energy with an alternating current than with a continuous current. In a lead-covered cable the loss in the lead envelope, even when the two extremities are connected (Fig. 2), is only 1 or 2 per cent of $C^2 R$, as no hysteresis is produced and the magnetic field is feeble. We then worked with a cable covered with lead, then with hemp, then with iron wire, and lastly, with a material impregnated with pitch. When the cable is laid in trenches, the tarred material does not insulate, so that the iron is to earth throughout its length; this is why, after having left the sheathing insulated upon the earth by the tarred cloth, I connected the two extremities of the

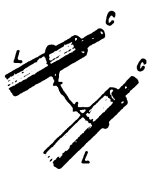

Fig. 2.

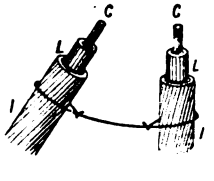

Fig 3.

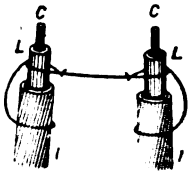

Fig 4

C = Copper. L = Lead. I = Iron.

iron by a wire of slight resistance (Fig. 3). As the lead is only separated from the iron by very weak insulation, they may also be connected. In order to make the conditions as unfavourable as possible, I connected the lead and iron by a copper wire, and then the two sheathings together as shown in Fig. 4. The following are the figures:—

Insulated sheathing

$$\frac{p}{C^2 R} = \cdot 18.$$

Extremities of the iron connected

$$\frac{p}{C^2 R} = \cdot 28.$$

Lead and iron in parallel, sheathings connected,

$$\frac{p}{C^2 R} = \cdot 35.$$

When the sheathing is insulated, only hysteresis and Foucault currents are produced, and the ratio is but ·18. When, on the contrary, the sheathing forms a closed circuit, it constitutes the secondary circuit of a transformer; a current is developed in it which is all the more intense, since the resistance of this circuit is feeble: thus, with the sheathings connected, the ratio is from ·28 to ·35. It may be remarked that the last case is not frequent in practice, for the resistance between the iron and the lead can never be altogether disregarded. Thus, ·35 is a maximum.

These figures relate to a current of 3,000 periods per minute. With currents of 6,000 to 7,000 periods per minute, the loss in the covering would evidently be greater. We may say that the loss in the envelope of a lead-covered cable is from 2 to 3 per cent.; while in a cable covered with lead and iron, the loss in the covering reaches the high maximum of 45 to 50 per cent. of the power dissipated in the conductor itself. Now it must be remarked that alternate-current cables are almost always traversed by

* From *l'Electricien*.

Digitized by Google

currents of high tension, and that the loss in the conductor never reaches more than 5 per cent. of the total power produced by the machines. Considered from this point of view, the additional loss due to an envelope of lead may be entirely disregarded. In a lead and iron cable the loss due to the covering is at its maximum 2·5 per cent. of the total power of the station.

It follows from these experiments that it is always more advantageous to employ simple cables, even when armoured, than concentric cables, and that there is no need to fear a detrimental effect upon the neighbouring telephone lines. In fact, the loss due to this cause is comparatively slight, and the mains cost half as much. The advantage becomes incontestable when we only employ a covering of lead, since a simple cable of this nature does not expend appreciably any more power than a concentric cable. In practice, we can in many cases content ourselves with a tube of lead, and substitute for the iron armour another mechanical protection, such as an earthenware tube or a tube of impregnated wood.

THE ENERGY-RELATIONS OF GAS AND ELECTRIC LIGHTING.*

BY DR. HENRY MORTON.

During the past ten years most of the brightest minds among inventors have been occupied with the problem of the production of light from electricity, and immense progress has been made in the way of improvement in this department, but relatively little attention given to the development of light by direct combustion. In both the best incandescent lamp and the best gas-burner the losses are enormous, and the possibilities of improvement immense.

Consider, first, the "mechanical equivalent" of light. In 1865 Prof. Julius Thomsen, of Copenhagen, showed that it was about 12·28 foot-pounds per minute, or 749 foot-pounds per hour, for each candle. Mr. M. G. Farmer, however, proved years ago, as the result of certain experiments made at Boston with an electric light, that it was about 10·1 foot-pounds per candle per minute. This would give an average of 11·29 —say 12—foot-pounds per candle per minute. If 1 candle-power per minute represents 12 foot-pounds, 1 candle-power for an hour would be equal to 720 foot-pounds in the same time. This being the "mechanical equivalent" of light, however produced, the question is to find out what proportion of the total "mechanical equivalent" latent in a cubic foot of ordinary illuminating gas is converted into light by burning in a standard gas-burner. Taking the Hoboken gas for the purpose of my investigation, I ascertained that it gave 640 heat-units per cubic foot. This, multiplied by Joule's equivalent of 772, gives 493,080, or in round numbers 500,000 foot-pounds. Burning in a Sugg standard burner so as to give the light of 16 candles, Hoboken gas would be consumed at the rate of 4 cubic feet per hour. This gives an efficiency of 4 candles per cubic foot. Each cubic foot will, therefore, give 4 candle-power for an hour. Consequently each cubic foot so burned would, in an hour, give out light equal to 2,880 foot-pounds; and this is the total energy of the light developed. While it is giving out the 2,880 foot-pounds of light energy, it is at the same time giving out the 500,000 foot-pounds as the total energy of combustion. The percentage of light energy to total energy is thus 0·6 per cent. This shows that the Sugg burner turns the available total energy into light energy by a method which is very wasteful. The Welsbach burner was then tried, and its efficiency was found to be 1·4 per cent.

In the case of the incandescent electric light, the following figures were found. Assume that practically we can get 10 lamps of 16 candles each for each horse-power expended. This figure will make, for each horse-power, 160 candles. Now, at 12 foot-pounds of energy per candle per minute in the form of light, this would give us 1,920 foot-pounds of energy per minute, in the form of light, from these incandescent lamps. A horse-power expresses 33,000 foot-pounds per minute. Comparing these numbers, we get 5·812 per cent. of the total energy developed as light, instead of ·6 per cent. in the case of the gas-burner. In other words, in the electric lamp we have about ten times as much of the total energy usefully converted into light as in the ordinary gas-burner.

Going back to the coal as the source of energy, however, we are at once confronted with this other condition: In the steam-engines used for running electric light plants (and this is not the result of mere guess, but of a number of measurements which have been made at the Stevens Institute, by various members of its faculty, on electric light plants), we utilise only about 5 per cent. of the energy of the coal used to produce the power applied to develop the electric current. On the other hand, in gas making I think it is fair to say that there is not any greater waste in the production of gas from coal than 50 per cent.; and therefore you get into the gas 50 per cent. of the energy of the coal. From this you will see that there is here the same ratio (1 to 10) between the gas and the electricity, only it is turned the other way. In order to turn the coal energy into motion (as in using the steam-engine to drive an electric light plant), we throw away 95 per cent., and only ulilise 5 per cent.; in order to turn coal into gas we throw away 50 per cent. and utilise the other 50 per cent. So that, getting 5 per cent. in one case and 50 in the other, the proportion is as 1 : 10. This brings the two systems to an equality again; for, starting with the coal, about as much of the total energy of the fuel is developed by the ordinary gas-burner as by the electric lamp. Thus, starting with the coal pile, and considering merely the question of the conversion of coal into light, one process is about as wasteful as the other at present.

* Abstracted from the *Stevens Indicator*.

THE BATH ELECTRIC LIGHT STATION.

The station building, now nearly completed, consists of two parallel rooms. The engine and dynamo room is 150ft. long by 40ft. wide, the boiler room is 100ft. long by 40ft. wide. Besides these rooms there are separate offices and test rooms, whilst over the front portion of the building there are three upper floors for stores and workshops. The premises have an unique situation for the supply of coal and other stores. The frontage is on a good main road, the river Avon runs at the back, on one side is the Great Western Railway station, on the other is the wharf of Messrs. Gerrish and Co., canal carriers.

The first instalment of plant now being erected consists of the following:—Two Babcock and Wilcox boilers of 150 horse-power each, working at a pressure of 140lb. per square inch. These supply steam for two of the Brush Electrical Engineering Company's compound engines, each of 150 indicated horse-power, and also four of that company's compound engines of 30 horse-power each. These engines are supplied with variable (hand) expansion gear. The exhaust steam is carried to a surface condenser, which is worked by independent pumps. The water is fed to the boilers by means of a donkey pump, but, as a reserve, an injector is placed on each boiler. The two large engines drive two Mordey alternators of 75,000 watts each. The four small engines drive four Thomson-Houston 50 arc-light dynamos, supplied by the firm of Messrs. Laing, Wharton and Down.

The mains for the district which will be supplied with electricity at once will require 40 miles of wire. These mains are being laid underground by Messrs. Callender and Co. The whole of the district, comprising 50 streets, squares and crescents, which is to be supplied, will be lighted by Thomson-Houston arc lamps from the 25th of March next, Mr. Massingham's contract with the local authority being for a term of seven years from that date. The arc lamps will be suspended over the streets from brackets placed on iron columns 30ft. high, the arc being 24ft. from the ground, this distance having been found the most effective at Taunton.

The size of the station provides for 2,000 horse-power in use, with ample spare power, and there is every reason to believe that all this power will be wanted within a few years.

LONDON CHAMBER OF COMMERCE.

Meeting of the Electrical Trades Section.

A meeting of the Electrical Trades Section was held on the 28th inst., Major S. Flood-Page, Vice-Chairman, presiding.

The following reportwas read:—

THIRD REPORT OF THE CORRESPONDENT.

Overhead Wires.—Three meetings of the Committee were held, and Major Cardew was consulted on several occasions by the Correspondent and by other members of the Committee about the interpretation and modification of the rules. A letter was written to Mr. Courtenay Boyle asking for certain minor changes. The alterations effected by the action of the Chamber were in the definition of "low pressure," which was altered from 300 volts to 600 volts if the system be earthed in the middle, and in the definition of the materials to be used for insulation, the word "india-rubber" being omitted. It is believed that the Board of Trade are instituting tests of silicium and other bronze wires, with the view of granting further concessions, if possible, for wires taking their own weight, without bearers, but at a full meeting of the Council of the Institution of Electrical Engineers, on the 25th inst., it was decided that they were not at present prepared to recommend any alteration of Rule 12.

British Association Screw Thread.—186 circulars were sent out, and only twenty replies were received. These came to hand just

Digitized by Google

before the meeting of the British Association at Newcastle, and as the Association exists practically for only one week in each year, except for purposes connected with its own organisation, a letter was written to the Secretary of the Mechanical Section, giving an analysis of the replies, in the hope that the Association might take some steps to popularise the matter. It appears, however, that as the Screw Thread Committee has been dissolved and the Committee of the Section is merely constituted to arrange the Papers to be read at the meetings, no notice was taken of the communication.

When the Post Office decided to adopt the British Association thread in the construction of its instruments, Mr. Th. Lehmann, of 28, Hampshire-street, Torriano-avenue, N.W., was appointed to manufacture the taps, screw-plates, and dies, and to supply them to the Post Office. Of Mr. Lehmann, whose name is not familiar in engineering circles, it is sufficient to say that he was formerly manager to Mr. Stroh, and superintended the construction of the most accurate work on the instruments for the Telegraph Department of the Post Office. At the invitation of the Correspondent, a box containing a set of tools is exhibited by Mr. Lehmann. Mr. Preece has kindly lent a sample set of tools, and a case containing a sample of every kind of screw used by the Post Office. Messrs. Davis and Timmins also exhibit samples of screws.

Standardising Laboratory.—At the request of the Board of Trade, 212 circulars were sent out, and thirteen replies containing returns, together with six blank forms with letter explaining reasons for not replying, were received. The totals were as follows: House-meters, 1890, 6,160; 1891, 13,100. Ammeters, 1890, 400; 1891, 581. Voltmeters, 1890, 556; 1891, 891. A letter containing these totals was forwarded to the Board of Trade, calling attention to the fact that only two supply companies had been able to estimate their requirements. With regard to the establishment of a laboratory, it is believed that Her Majesty's Treasury continues to give the matter its most careful consideration.

Messrs. Davis and Timmins informed the meeting that the replies to the circulars gave a very erroneous idea of the extent to which the British Association screws are being used, and added that the circular had stirred the matter up, and had produced further inquiries.

Mr. Trotter said that the circular on the Standardising Laboratory had been greatly misunderstood by instrument makers, who did not seem to be aware that all instruments used in connection with the sale or supply of electricity would have to be certified, or their indications could not be taken as evidence in case of dispute. One of the replies stated, "We have at great expense fitted up at our works one of the most perfect standardising laboratories in England: we should have no use for the one you refer to." Another says: "There are a considerable number of instruments sold by us, and at prices above what similar instruments can be bought at, because of the reputation of our testing staff and appliances, and the recognised accuracy of the results. If this laboratory is established, it will certainly benefit newer firms who have not the same reputation; but we fail to see that we should be likely to get an enhanced price—indeed, the opposite would probably be the result."

In the absence of Mr. Crompton and Lord Crawford, the question of the Metropolitan Building Act was not discussed, but it was explained that the Metropolitan Building Act, formerly administered by the Metropolitan Board of Works, allowed a certain amount of discretion to their surveyors, by which they could have dispensing powers for certain items. The County Council now prohibited all such dispensing power, and all departure whatever from the letter of the Metropolitan Building Act had to be referred to the County Council itself.

Mr. Murray (Secretary of the Chamber) reported with regard to the commercial education scheme, and scholarships, and prizes.—Mr. Price thought it would be a good thing if young lads were brought up a step further than the ordinary run of education if they intended to go in for electrical work. He thought scholarships and prizes given for electrical work would be most desirable.—The Chairman said they generally approved the action of the Council in the matter.

In connection with railway rates, Mr. Murray reported that the case for the Electrical trades would not come on at the Board of Trade inquiry for some months, and in reply to a question, stated that most of the objections raised by the Section were identical with those of other Sections, and would be taken altogether.

Major Flood-Page (the Chairman) said he had a matter of very great importance to bring forward. It had been determined to have in Edinburgh what was called an International Exhibition of Electrical Engineering, General Inventions, and Industries, to be held next year. Some of the rules which had been drawn up were very stringent. He thought that the time had come when everybody connected with the electrical industry should speak out. They would agree that exhibitions, especially when 400 miles away, were very expensive. They got very little out of them, and it was neither fair nor reasonable that gentlemen in Edinburgh who wanted to make money for the people there should call upon others to bear the expense which was necessary for such an exhibition. If the electrical profession responded, the amount that they would have to expend would be measured by tens of thousands of pounds. It was within his own knowledge that one firm had spent about £6,000 in connection with one exhibition, and yet they were not able to trace a single order from it. He would therefore suggest, not that they should not exhibit, but that they should exhibit on their own terms, and not on the terms of the exhibition authorities. He would like to point out that an electrical exhibition could not be successful without the help of the Electrical Trades Section; in fact it could not be undertaken if they chose to stand out, for they embraced almost the entire electrical world. However, they were now called upon to pay for space, delivery, arranging, cost of installation, and insurance. It was time that they should arrange to have free rent, free power, and free current. If they asked for that which was fair and reasonable, and if they were united, they would be taken on their own terms or there would not be a successful electrical exhibition. He then moved the following resolution:

"*That with a view of the electrical industry taking common and united action with regard to the proposed Electrical Exhibition in Edinburgh in* 1890, *a committee be appointed to consider the conditions on which it may be advisable to take part in the exhibition, and that a meeting of the Electrical Section of the Chamber be called for Monday,* 14*th November, to receive the report, and if thought advisable to take action thereupon.*"

Mr. Swinburne seconded the motion, which was carried, and the committee was then formed.

OCEAN CABLE REPAIRS.

The following article from the New York *World* may prove of interest to some of our readers who are not acquainted with the work of cable repairs:—

The idea of the broken ends of these cables, lying hundreds of fathoms deep beneath the track of passing vessels, and hundreds of miles away from land on either side, appeals in a peculiar way to the ordinary imagination; and it appeals to the imagination of anyone who knows fairly well what the bottom of the ocean is like more strongly still than it does to a person who has a prevailing notion that the bottom of the ocean is all sand and extends pretty much like a billiard table from one continent to the other. But fancy for a moment a cable strung across the mountains of this continent and dropping into the valleys by sheer force of its own weight; falling from the pinnacle of Mount Washington and trailing across the Hudson River, climbing the Alleghanies and the mountains of Tennessee and dropping thence into the valley of the Mississippi, winding across the plains and climbing the Rocky Mountains on the way to San Francisco, and then flood this immense area with a mighty ocean, and a practically faithful picture of a deep-sea cable is presented. Starting from land on the other side, these Gould cables descend into the valleys, reach up to the tops of the hills, turn and twist and go around and climb across; and fathoms and fathoms above them the waves break themselves against each other, and storms lash the waters into fury, or the sunshine spreads them out serene and placid as a mirror. And it is the picture of these broken cables, broken half-way down a hill, or buried in the sands half-way across the valley, that captivates the fancy and makes one wonder over the science of man, which enables him to pick up those ends from the mysterious depths of ocean and put them together again. The location of a cable break can be very accurately determined by electricians. After having found out how far from land the break is, the only other thing the captain or navigator of the cable steamer wants to know is in what direction that distance is to be travelled; and as the course of the cable is perfectly well known from the fact that when the cable was laid accurate observations were taken by the cable layers and records made, the cable steamer starting out to do the repairs can steam directly over the spot where the break is located. Of course, when this statement is made, it is not at all meant that the location can be determined within a few inches or a few feet, but it can be determined within a very limited area, so that the grappling for the ends of the cable does not usually extend in good weather over a period greater than two or three days, and sometimes does not last even so long as that. The grappling-irons are immense affairs, attached themselves to cables manipulated from the deck of the steamer, and are plunged downward and dragged over the bottom of the ocean. When the cable is finally grappled the fact is made clear at the steamer end of the line by reason of the strain to which the grappling-iron is subjected. The strain is revealed by an instrument on board the steamer known as a dynamometer. When this instrument reveals the presence of such a strain as the grappling of the cable would bring about, the iron is hauled up with the cable at the end of it. The repairers always calculate to grapple the cable about ten miles away from the point at which the break has occurred. If the irons grappled the cable too near the end, the cable would slip away long before it reached the deck of the steamer. In some instances no break has occurred at all, and electrical communication has been interrupted perhaps by the destruction of the insulated covering of the cable, or by some defect of a similar character, so that when the grappling-iron appears at the surface of the water, the entire length of cable comes

Digitized by Google

up with it. The break is then spliced, or the defects remedied, and the rehabilitated cable is consigned once more to the bosom of the mighty deep. Of course, many times it is not possible to determine exactly what the cause of a cable break has been, but usually the trouble is that the cable has been laid too taut, and it has broken or been damaged in a serious way by reason of the immense strain resulting on this excessive tautness. The consequence is, that whenever a repair is made in mid-ocean the repairers cut away all the twisted and strained cable in the immediate neighbourhood of the break, and do away with all possibility of tautness by putting in 25 to 50 miles of new cable. This may meander down the side of a submerged Mount Washington, or may curl quietly up in the basin of a Mohawk Valley, but, whatever it does, there is no chance of the cable breaking in that particular spot again from being drawn too tight. Outside of this, cables are frequently damaged by the anchors of vessels, fishing vessels chiefly, which anchor for the purpose of carrying on their fishing. Accidents of this kind occur, of course, near the shore or the banks of Newfoundland. The anchor becames entangled with the cable, and, rather than spend the time necessary to get it free, the cable is dragged up and cut, and the vessel proceeds on its way. Simply to avoid a little trouble the captain of a fishing vessel will put a cable company in for thousands of dollars of expense. The situation is recognised by the cable companies, and they have a standing offer to indemnify any vessel for the loss of an anchor, and they pay out large sums of money every year on this score. It will be seen that there is no possibility of verifying such claims, and the consequence is that false claims for damages have undoubtedly been put in and unscrupulous captains have collected money for anchors which were never lost. Another source of trouble to the cables are the icebergs. These icebergs, floating down from the arctic seas, frequently extend beneath the surface of the ocean for many hundreds of fathoms, and the base of the passing iceberg catching the cable bears it onward and finally snaps it in two. The bottom of the ocean varies in depth in a very marvellous way, right in the path these icebergs usually take. Off the banks of Newfoundland the bottom is reached sometimes at so inconsiderable a depth as 75 to 100 fathoms. But from the point where the depth is 100 fathoms the ocean bottom goes down the side of a mountain to 2,500 fathoms, or two miles and a-half, within a very short distance. Perhaps the bottom rises up again and the cable hangs between the two submerged mountain tops, and the iceberg coming along quietly picks up the loop thus formed and carries it onward until the strain results in an absolute rupture. There are stories of cables having been injured by whales and other monsters of the deep, but these interesting tales are to be taken with a good deal of allowance. One tale is to the effect, and it is a tale in more senses than one, that when a faulty cable was once dragged on deck the decomposed body of a whale was found within the twisted and convoluted cable, and electrical communication had been interrupted because the cable had got around the whale and the whale had got around the cable. This Munchausen story may be true, but it cannot be verified. Another fairy tale which has attained limited circulation is that a mid-ocean cable was attacked by a sword-fish, the sword-fish labouring possibly under the impression that the cable was an elongated eel, and the result of the attack was that the cable was peeled of its outer covering and the bare wires were left to the mercy of the immediate and watery surroundings. All the cable companies regard cable breaks as a part and parcel of their legitimate business. They are never surprised when a misfortune of this kind overtakes them, and, so far as financial considerations are concerned, they are always prepared for it. Indeed, all the companies put away so many thousand dollars every year to pay for anticipated breaks of this character, so that the money which goes for repairs does not come, so to speak, directly out of the treasury. It has already been appropriated for the purpose to which it is applied. The only break which the cable people really dread is the break which occurs not in mid-ocean but in mid-winter. It is quite obvious that the repairing of a deep-sea cable, when the waves are rolling mountains high, is no easy task, and under these circumstances grappling for a cable is something very difficult of accomplishment. In the summer, though, and particularly in October, after the equinoctial storms, when the skies are serene and the surface of the ocean frequently as placid as the surface of an inland lake, the matter of repairing the breaking of a cable, unless, indeed, it interferes seriously with business, is not regarded in so serious a light.

The cable buoy is used in repairing cables if the break happens in winter time and a storm comes up and begins to hustle the steamer around in such a way that it isn't possible to keep the end of the restive cable on board. At such a time as this the cable is attached to the cable buoy and the buoy is thrown overboard. When the weather subsides the cable is easily recovered, and the splicing is done. Of course, as soon as the cable is found, communication is established between the steamer and the cable station on one or the other side of the Atlantic. If the communication between the steamer and Ireland is all right, for example, it is known that the cable is uninjured between those two points, and when this has been determined the repairing goes on until the American side of the ocean and the steamer are brought into electrical contact. It may be mentioned that in grappling for a cable with the grappling-iron, the steamer proceeds in a course exactly at right angles to the cable, so that the cable is usually caught within a comparatively short time."

Of course the cost of repairing a cable is very considerable. When it is considered that a fully-equipped ocean steamer, with an expert navigator and expert electricians on board, is devoted exclusively to the business of repairing the cable for a length of time extending anywhere from two weeks to a month, some idea of the cost may be arrived at. The Commercial Cable people have their own steamer, which represents an investment of several hundred thousand dollars, and the officers and electricians are on the pay roll of the company from one year's end to the other. The Anglo-American Compary, which owns four cables in the pool, also has a cable steamer, called the "Minia." The Western Union people have no steamer of their own, and when they need a steamer hire either the "Minia" from their associates in the pool, or the "Faraday," which is owned by the Siemens Brothers, of England, who maintain the "Faraday" because they are cable manufacturers, and use the steamer as a general thing for laying new cables. When the "Minia" is hired out its owners charge $800 a day for it, and when the Siemens Brothers have the "Faraday" at liberty their daily rental is $1,200. As three weeks is perhaps an average time required for the proper repair of an ordinary cable break, it will be seen that the mere rent of the steamer amounts to about $25,000. To this is to be added, of course, the actual cost of the repairs and the 25 or 50 miles of new cable. And cable, if it were sold by the yard, would be sold almost at the price of fine lace. The two cables which the Western Union intends laying from Nova Scotia down into New York Bay, a distance of 840 miles, will cost, with the laying, about $1,600,000, and presumably the cost of laying bears the same relation to the cost of the cable as the cost of carpet-laying does to the price paid for the carpet. Some cable breaks have probably cost $100,000, but it will be seen that the cost is entirely dependent on conditions which cannot be foreseen and cannot be controlled. A foggy day with the "Faraday" in commission means an absolute expenditure of $1,200, and a week of foggy days will bring this up nearly to $10,000, both from the fact that observations cannot be taken in bad weather, and from the fact also that successful grappling cannot be conducted when the surface of the ocean is disturbed unduly by storms; clear, bright weather is almost absolutely essential to the prosecution of repairs.

The finding and repairing of the original Field cable is probably the most remarkable triumph in the whole annals of the science of navigation. When that first Field cable was laid nobody knew as much about cable-laying as they have since found out, and no particular or especial pains were taken to record the exact course of the steamer and consequently the location of the cable. It parted in mid-ocean, and for five years no attempt was ever made to do anything with it. At the end of that time, and after a second and more successful cable had been laid, the "Faraday" steamed out on the trackless ocean to pick that cable up, did pick it up, spliced it, and finished successfully the job of laying it. Here certainly the difficulties in the way seemed overwhelming. The only thing the searchers had to guide them in their search was the log of the steamship "Great Eastern," which made known the course of the vessel certainly, but not with the extreme accuracy which was in such a case every way desirable. More than that, the cable had lain at the bottom of the ocean for five years, and probably the grappling-irons passed over it a number of times before they finally grappled it. When it was got hold of it was incrusted with all manner of ocean growths, and Cyrus W. Field is said to have a piece of it about a yard long covered with coral. When this successful achievement is considered, the work of finding and repairing a cable, where the break is known to be a certain number of miles from the land and the original course of the cable is a matter of accurate knowledge, dwindles into comparative insignificance.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 19, 1889.

Since my last letter to you the city of New York has been in a state of turmoil, agitation, discussion and indignation over the question of putting the electric light wires underground. The whole matter originated with the killing of a Western Union lineman on a pole quite close to the City Hall and the Courts, just about middle day, when the streets were fullest of passers-by. This lineman appears to have gone at his work in the ordinary way without taking any precautions to ascertain whether the wires were clear of current or not, and, it is said, not only with bare hands but with bare arms. Be this as it may, he had not been on the pole very long before he was seen to have succumbed to a shock, and some delay occurred before his smoking body, around which an arc played, could be removed. If this had occurred in the outskirts of the city probably little more than usual would have been heard about it, but as it was within a stone's throw of all the newspaper offices, the reporters immediately swarmed thither, and the consequence was that that night and the next morning New Yorkers were regaled with one of the most sensational dishes of horrors that can well be imagined. Thereupon sprang up a great and unreasoning popular clamour, which reacted at once on the somewhat lazy Subway Board, and which encouraged the Mayor to pose once again in the attitude of a popular reformer, determined to protect the people's welfare, at whatever cost. He immediately wanted every one of the circuits stopped and chopped down, and probably would have had his way by this time had not the Courts interfered to protect the property of the companies. Not only has the Subway Board been stimulated to activity in the matter, but other authorities have felt that they were called upon to interfere. The Park Commissioners, as they do not

Digitized by Google

expect to return to the use of the electric lights until the wires are buried, have requested the Department of Public Works to put gas lamps in the small squares and parks down town, and the Board of Health has gone so far as to pass resolutions recommending that continuous currents above 700 volts and alternating currents above 250 volts shall be forbidden. In the meantime a great many more of the poles have been chopped down, but, under the protection of the injunction of the Court, the companies whose circuits were in bad order have been putting up new wires. It looks as though the outcome of the whole agitation would be not a resort to lower potentials, but a more general resort to the conduits, and, in view of this probability, a great deal of interest is felt in the control of the subways. The Consolidated Telegraph and Subway Company, which has done all the subway work thus far of a general character, under the authority of the Subway Board, has, according to Mayor Grant's view, not been expeditious enough in its work, and he has sought to annul its franchises for that reason. There can be no doubt, of course, that a great many of the arc light wires in this city have been in bad condition, but there are many excuses to be offered for the companies in spite of their faults, and one of these excuses is that they have not been allowed to keep up their circuits as they desired, even where there were no subways to go into, and that where there were subways to go into it was hardly likely that they would rush into them when they had to pay $800 a mile. As I have said, however, we shall now probably see a rapid extension of subway work, and a great many of the electric light wires, arc and alternating, placed in them. This will probably satisfy the public, and perhaps silence some of the newspapers which have been talking so foolishly on the subject, but I am afraid it will not very greatly improve the conditions for the linemen, who certainly should be safer on poles than they would be in narrow little manholes, where the connection to ground through the damp earth and brickwork is about as complete as one could well make it. Of course, the reporters have been flocking in large numbers to Mr. Edison to ascertain his opinion on the subject, and he has naturally once more reiterated his well-known views in favour of low tension; but it is to be borne in mind, as has been pointed out, that the Edison parent company not only employs the Edison municipal system at 1,200 volts, but has lately been recommending its sub-companies to go in for arc lighting on the series system, so as to withstand the pressure of competition.

Another interesting piece of news of the week is the acquisition of the control of the Brush Electric Company of Cleveland by the Thomson-Houston Company of Boston. This is another of the great consolidations that have been on the tapis for some time past. Although little is as yet known as to the terms of the arrangement, it is said that the consideration is at the rate of $3,250,000 for the whole property. It has been understood for some time past that Mr. George Westinghouse has himself been seeking to acquire this valuable and desirable piece of property, and when recently he bought out the local Brush Company in this city, it was supposed that the first step in the matter had actually been taken. It now appears, however, that the Thomson-Houston Company have got the better of him, although perhaps it may be that Mr. Westinghouse did not care to go quite so high in the matter of price, and considered that he could get along better without the purchase. This last move leaves but three large companies for electric lighting manufacture in the field, and it may reasonably be supposed that matters will end there, there being apparently no love lost between either the Thomson-Houston, Westinghouse or Edison interests. It is possible, therefore, that the triangular duel *a la* Midshipman Easy may be fought out for some time with a great deal of bitterness, and then——

One of the financial papers of this city states that the Electrical Accumulator Company, in a circular signed by Mr. Theo. N. Vail, its president, has proposed to its stockholders a plan of reorganisation which shall take over the property and business of the old company, and some $300,000 is required to carry on the business and liquidate the outstanding indebtedness. At the present time the capital stock of the old company of $5,000,000 is stated to be wholly issued and fully paid, while of another issue of $1,000,000, $617,400 have been sold and $235,000 have been hypothecated. There seems little reason to doubt that, although the company has spent a large amount of money in its work, it will effect its reorganisation and carry on the business, which, in spite of many drawbacks, seems destined to develop and grow steadily, if not rapidly.

There is great and continued activity in the development of electric railroading, and the Convention this week at Minneapolis of the street-railway men will doubtless bring out many interesting and encouraging facts with regard to this new application. The electric railroading schemes are actually getting colossal, as an instance of which I may mention the long-distance road it is now proposed to put in between Seattle and Tacoma, in Washington. This road will run a distance of not less than 30 miles, the power being furnished by four stations along the road. It is understood that large local bankers are interested in the project, and there seems reason to believe that the scheme will be carried out. With regard to the general development in this field, it is interesting to note that a table, published by the *Electrical World* this week, shows that there are no fewer than 179 roads, or extensions of roads, built or under contract in this country, with an aggregate of 1,260 miles of track and 1,884 cars. In a great many instances the details of the table are supplemented by statements as to the cost of operation, and it would appear that the cost of power in every instance reported upon is far below that of animal locomotion. Many of the companies speak enthusiastically about the service and system, and give evidence of their faith by going in heavily for an enlargement of their line and equipment.

At a meeting of the American Institute of Electrical Engineers this week, Mr. Thos. D. Lockwood, the well-known electrician and patent expert of the American Bell Telephone Company, read a very interesting Paper, descriptive of his recent travels through England and a portion of the Continent, and of his observations on what was being done in the electrical field. Although Mr. Lockwood has been credited with the possession of genuine Transatlantic humour, he is an Englishman born and bred, and although he makes a first-class American, his English characteristics are such as to be immediately recognised by those who come in contact with him, especially if the contact happens to be stand-up fight. Mr. Lockwood may, therefore, be taken to be a fair and impartial critic, and I think English electricians will be glad that he recognises the solid progress that has been made among them, even although it has not been so rapid as our own. In fact, Mr. Lockwood has long been known as the dogged enemy of the electrical Cheap Jack, and as the persistent advocate of good and thorough work, and hence he finds a great deal in England that is worthy of admiration, as compared with what can be shown here in the matter of hasty, scrambling construction. It is interesting to observe, however, that while appreciating the good points of the Government telegraph system in England, Mr. Lockwood is not in favour of a Government monopoly of the telegraph in this country, and that he is equally averse to any control by the official authorities of the telephone system. Mr. Lockwood was impressed, as most Americans are, with the absence of electric lighting on a large scale, but, as a telephone man, he was a little bit inclined, perhaps, to look upon this as a blessing in disguise. In the discussion that followed on Mr. Lockwood's Paper, Mr. G. L. Addenbrooke, of London, participated. That gentleman is now on his way home from Australia, where he has been engaged in electrical work. and he greatly interested his auditors by describing the methods of line construction in England, and especially those employed for the distribution of the Ferranti alternating currents at 2,500 volts from the Grosvenor Gallery plant.

The subject of electricity continues to occupy the attention of the non-technical Press in a remarkable manner, and we even find the papers and magazines for children publishing elementary disquisitions on this absorbing theme. *Scribner* accompanies next month its interesting series of articles on electricity by two Papers on electricity in war. One, on naval warfare, is by Lieutenant W. S. Hughes, of the U.S.N., and the other, on land warfare, is by Lieutenant John Millis, of the

Digitized by Google

Engineering Corps. These two Papers will be copiously illustrated, and will show how much electricity has done in the way of perfecting the processes and appliances to the "abominable end of annihilating mankind." While these Papers do not embrace much that would be novel to your readers, they put together compactly all that has been done up to date. Lieutenant Hughes mentions the fact that the incandescent plant on the "Trenton" was, so far as is known, the first of its kind in the navies of the world, and he also points out that it has been left to the United States to take the initial steps towards the introduction of electric motors on men-of-war by placing them on board the new steel cruiser "Chicago," where, if I am not mistaken, they not only work one of the 18-inch guns, but run a shot-whip or hoist. Lieutenant Millis, whose Paper in some respects will overlap that of Lieutenant Hughes, devotes an interesting section to the subject of torpedoes, illustrating his remarks by views of the Sims-Edison electric torpedo, as started from the shore, and making its way around or under obstacles intervening in its path. Yet another article of general interest is that which has just appeared in *Harper's Weekly* on the subject of electricity as applied to street-car propulsion. This article is written by Mr. H. L. Nelson, and goes over the whole ground of what has been done in recent years. Mr. Nelson presents the point very clearly that operating by electricity is economical for street railways, and that one of the noticeable features has been the wonderful increase in traffic along the electric lines, as well as the advance in the price of real estate.

Speaking of electric railways reminds me that on one of the new roads that has recently gone into operation at Cincinnati, the word "motorneer" has been definitely adopted for the drivers of the cars. Each of the men in charge of a motor-car, or a locomotor, has a band around his hat with the word "motorneer" on it. This new coinage is not a very elegant one, nor is it very generally liked, but it seems to be adopted out of sheer force of necessity, and partly, perhaps, because it has some sort of rough phonetic analogy to "engineer." This road is also somewhat of an original one in its method of operation. It runs from the very heart of Cincinnati, where its overhead wires are carried past some of the finest buildings without in any way disfiguring them, to the foot of an incline. Then the cars are hoisted on elevators to the top of the bluffs that dominate the city, and thence they run by electricity through the suburbs out to the well-known Zoological Gardens. The president of this road, it is worthy of mention, is Mr. H. H. Litell, an old and well-known street railway man, to whom belongs the credit, I believe, of founding the American Street Railway Association. The fact that such a man is actively and enthusiastically interested in street railways tells its own story.

BRUSSELS NOTES.

(FROM OUR CORRESPONDENT.)

BRUSSELS, *October* 22, 1889.

Belgian electrical exhibitors at the Paris Exhibition have, I am glad to say, come off with their fair share of awards. Gold medals have been awarded to M. Julien Dulait, of the Société Électricité et Hydraulique, of Charleroi, to M. Joseph Jaspar, to the Société Anonyme l'Électrique, to the Société Anonyme Franco-Belge d'Appareils d'Éclairage, of which M. Bandsept is managing director, and to M. Van Rysselberghe. Silver medals were also awarded to MM. Courtois and Emile Gérard, and to the Société Anonyme Belge pour l'Éclairage et Transmission Electrique á Longue Distance, in addition to which a bronze medal and an honourable mention were obtained.

M. Van Rysselberghe's proposals for the lighting of Brussels, about which I spoke in my last letter, did not meet with much favour in the eyes of the Special Committee, who listened to further explanations from M. Van Rysselberghe a few days ago. The Burgomaster and several councillors were present at the sitting, and it was generally understood that these proposals had been rejected. M. Van Rysselberghe, however, still keeps his ideas before the public, and a second *brochure* from his pen has appeared, in which he vigorously attacks the system employed at Berlin, insisting on its costliness and the danger arising from a collection of high-pressure boilers placed in the midst of a densely-populated district. If a high tension system of electrical distribution were employed, I am inclined to think that most of his remarks would lack point.

The works of M. Julien Dulait, at Charleroi, have lately been considerably enlarged, and a carbon factory has now been added. The shops are very busy, and night-work is necessary to keep pace with orders.

October 28, 1889.

The Special Committee have decided to advise the town authorities to divide the town into two areas for electric lighting purposes, each of which will be allotted provisionally to a concessionnaire with a view to testing his system on a large scale. One of the concessionnaires is to be M. Van Rysselberghe, who will, therefore, have an opportunity of showing what his hydro-electric plan is capable of. The second area will be allotted to whichever company offers the best terms. When the provisional concession has expired it is proposed that the concessionnaire whose system is decided to be the worst shall hand over all his rights to his successful rival. It will be interesting to watch the outcome of this proposition.

A small Tudor accumulator station has just been opened at Ghent. At present the capacity is only 900 20 candle-power lamps, but a second battery, doubling the output, will shortly be erected. The charging is effected by Tudor dynamos running at 900 revolutions, and having an E.M.F. of 160 volts.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *October* 28, 1889.

The Swedish State Telephones are contemplating taking another important line in hand very shortly, viz., between Uddevalla-Vennersborg and Gothenburg. This line is one of the six main telephone lines to which the last Swedish Parliament voted a grant of 750,000kr. The length of the above line is 109 kilometres, and there will be a double 2·6 millimetre copper wire. Also, in Norway, the telephones are being greatly extended. Of new lines in the course of erection may be mentioned those between Drammen and Kongsborg, and between Christiania and Moss. The latter line, which is being installed by the local telephone companies in the two respective towns, pays 2,000kr. to the State Telegraphs as compensation for possible decrease in the number of telegrams passing between the two towns.

The Electric Engineering Company (Elektriska Aktiebolaget), Stockholm, decided at a recent general meeting to enter into co-operation with a new electric company for transmission of power. This new undertaking, which has just commenced operations, has its head-quarters at Arboga, Sweden, the firm being "Wenströms and Granströms Elektriska Kraftbalaz." Oddly enough, electricity has hardly at all been used in Sweden for power, although this country offers special facilities for installations of this nature owing to its enormous quantity of water-power. The various electrical firms have, however, been too busy with light installation to give much attention to the other department, so the new firm will probably find plenty to do. An electric railway at Boxholm will be its first work.

The various workshops and other buildings belonging to the Swedish artillery at Karlsborg have recently had electric light installed. The well-known firm of Palmcrontz and Co., Stockholm, are the contractors. There are two dynamos, for 200 and 150 lamps respectively, the out-door lamps being fed by accumulators at times when the inside lamps are not going. The Marieburg Ammunition Works are also to be lighted by electricity.

The Danish Government asks in its present Budget for several grants for electric lighting. One proposed installation is the electric lighting of the large Theatre Royal at Copenhagen, and it is the intention to light the entire building by electricity. For the interior 4,000 lamps are proposed. On the stage the incandescent lamps will be on what is called the three-lamp system, in which each light has lamps of three different colours (white, red, and green), which can be used entirely independently of each other. There has been some doubt whether the electricity should be supplied from an electric central station outside the theatre, or whether the theatre should have its own independent electric station, and the latter has been decided upon as by far the most satisfactory and most cheap.

At the Copenhagen Central Railway Station it is also proposed to introduce electric light, and the Government proposes an installation comprising 24 arc and 100 incandescent lamps. Several grants are also asked for the State telegraphs and telephones; for the latter 50,000kr., mostly for connecting fishing villages, &c. Inland express telegrams will soon be introduced in Denmark, and it is proposed to charge three times the ordinary fee for such messages.

CORRESPONDENCE.

THE PRACTICAL UNIT OF INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Professor Ayrton is, I think, under a misapprehension as to what the Paris Electrical Congress have stated in their resolution about the Practical Unit of Induction. In the copy of the Resolutions which was handed to the British Association Committee by Sir Wm. Thomson and Mr. Preece, and which I understood to be official, the word "secohm" does not occur, neither does it in the text of these resolutions, given in *L'Electricien* for August 31 of this year. The words are simply—

"L'unité practique de coefficient d'induction est le *Quadrant*, 1 quadrant = 10^9 centimetres."

Neither the Congress nor the B. A. Committee assert that a quadrant and a secohm are identical. Of course, if Prof. Ayrton defines secohm in terms of the "legal" ohm, they are not; though why he should adopt the "legal" ohm as the commercial unit of resistance I do not know. The B. A. Committee, it is true, in 1886, in reply to a communication from the Board of Trade, advised the Government "to adopt for a term of ten years the legal ohm of the Paris Congress as a legalised standard sufficiently near to the absolute ohm for commercial purposes," but that recommendation has never been acted on by the Government.

The practical unit of resistance in 10^9 C.-G.-S. units, and the practical unit of induction in electro-magnetic measure is 10^9 centimetres.

And now a few words as to the choice of the word "quadrant." In his article on the "Secohmeter" (*Nature*, June 9th, 1887, p. 131), Prof. Ayrton states that the commercial unit of induction is "about 2·3 in a thousand less than 10^9 centimetres, or one earth's quadrant," thus basing it on the legal ohm. He then proceeds, "Now, in spite of the difference between the two numbers, which, although small, it is a pity to lose sight of, the English word quadrant is not used in French, therefore it would not be well to suggest this word as the international name for the unit." He then goes on "to suggest secohm as a provisional name." It would appear from this that one main reason against adopting "quadrant" was the fear that it would not be recognised in France. At Newcastle, however, the B. A. Committee were brought face to face with the request to adopt "quadrant" because it had been adopted in France. Is it too much to expect that the authors of the word "secohm" should for the sake of international unity surrender their "provisional name" and adopt one which was at any rate mentioned in their original communication on the subject?

As to the definition of the term "Legal Quadrant" which Prof. Ayrton asks for, I should say that a legal quadrant is a length which bears to 10^9 centimetres the same ratio as the resistance of a column of mercury 106 centimetres long, 1 square millimetre in cross-section, at 0° C. bears to 10^9 C.-G.-S. units of resistance. The legal quadrant is thus the same as the secohm as defined by Professor Ayrton, if we assume as he does in his definition that the resistance of the legal ohm is ·99777 ohms.

There is one other point. I sympathise fully with what Mr. Sumpner says as to the suppressed dimensions of μ, and for this reason might have personally preferred a name which would not perpetuate the present incomplete state of our knowledge in a time when we shall come to know more about the nature of magnetic force and magnetic induction; but the fact remained that quadrant had been adopted at Paris, and the objection Mr. Sumpner has raised was not thought sufficiently serious to outbalance the advantage of a uniform nomenclature. The definition as given in the resolution of the B. A. Committee is strictly accurate. On the electro-magnetic system of measurement a coefficient induction is, and always will be, a length.—Yours, &c.,

R. T. GLAZEBROOK.

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the notes of your issue of the 18th inst., referring to Electric Traction, you evidently allude to my method of carrying cells, and say:—"There may be, probably there is, something to be said for it." Will you allow me to offer a few remarks, which I think will not be out of place at the present time.

Your electrical readers will not endorse all my views on this matter, but I have tackled the problem from a purely mechanical standpoint. It will be found that a set of 70 E.P.S. Co.'s 19 T cells, their latest traction pattern, having a capacity of 120 ampere hours, and a discharge rate of 40 amperes, will cover 38 square feet of floor—that is, without any carriages or cases for removing them from the car. The available floor space in an ordinary 46-passenger car, clear of all obstructions, is 14ft., or less by 14in. under each seat, 33ft. in all. This cramping of cells is, I maintain, the entire cause of the financial failure of storage cars carrying the cells under the seats.

I shall be told that smaller cells can be made to have a larger capacity and a higher rate of discharge, but at what cost to their life and efficiency? I find that those who have any knowledge of secondary batteries are almost unanimous in the opinion that the plates should be a much greater distance apart than was considered sufficient some year or two ago. I believe Sir David Salomons was the first to suggest increasing the space between the plates, and it has certainly been adopted by the cell-makers of to-day.

Again, it is impossible to run a car into the depôt, taking passengers and all, after every 16 or 20 miles' run, to change the cells, and as all depôts do not happen to be at the ends of the line where the cars are empty, a useless journey would have to be made for that purpose. The tender can be handled in the same manner as horses—run out to the car as it passes, not detaining it more than a minute. There is the further advantage that, once being packed in the tender, the cells are not subject to the rough handling and the sudden shocks they would get in withdrawal from the car, besides the advantage of being able to use a cell of such a size as will ensure a fair efficiency and life.

I quite agree with you that for storage traction two motors on each car are an absurdity; the cells will not stand the double discharge for any length of time, and two motors are of little use if you cannot use them.

The widely different conditions under which a car is required to work, in the London streets at least, makes it a necessity that some means of relieving the strain upon the motor as well as the cells should be provided, and I have adopted in my car two sets of gear, one having a ratio of 1 to 7, and the other 1 to 14; with the motor running at 700 per minute they give 7 and 3½ miles per hour approximately. In our experiments we found it answer very well indeed, by an automatic arrangement the car always starting with the powerful set. But having received some rather severe criticism upon my method of gearing, especially from an esteemed contemporary of yours—who, by the way, has never seen it—and not having absolute faith in my own infallibility, I have for some time past been experimenting upon a fresh method of gearing, retaining the two ratios as before, and I am glad to say with some measure of success, which I shall be only too glad to describe as soon as I find it to be absolutely reliable.

Respecting my double armature motor, I know very few electricians will admit it is necessary, although all makers of dynamos and motors manage to get the price of a "*spare armature*" into their price lists, and I have yet to learn that an armature wears out. I submit it is rather handy to have a spare one, which, by the movement of a hand-wheel, can be made to take the place of one that has been disabled or in danger of being damaged.—Yours, &c.,

Victor Works, Holloway, N. W. D. SANDWELL.

THE BIRMINGHAM EXHIBITION AWARDS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the awards recently given at the Birmingham Electrical Exhibition for "gas engines," several reports are in the papers in which we are not mentioned in any way. We should like to inform you that on behalf of Messrs. Crossley Brothers (Limited) we secured the Special Award Gold Medal, for the "Otto" gas engines, and enclosed have pleasure in handing you a letter from the secretary of the Exhibition, in which an explanation is given why our award (which is the highest) was omitted from the list sent to press.

Digitized by Google

We should esteem it a favour if you will kindly notice this in your next issue.

Thanking you in anticipation,—Yours, &c.

Birmingham, Oct. 30, 1889. JOHN WRIGHT AND CO.

[COPY.]

SIR: Permit me to explain that a special Gold Medal was awarded to Messrs. John Wright and Co. for the "Otto Gas Engine," by the jurors, but by some oversight their name was omitted from the preliminary list published in the papers. I very much regret such an oversight should have occurred, especially as it was considered that the gas engine exhibited by Messrs. Wright was entitled to the first place in the list of awards.—Yours faithfully,

T. C. SHARP,
Secretary and Manager, Birmingham Exhibition.

THE ZIPERNOWSKY ARC LAMP.*

The Ziperiowsky arc lamp, made by Ganz and Co., of Budapest, is shown in the annexed cuts. The fine wire solenoid E is a shunt

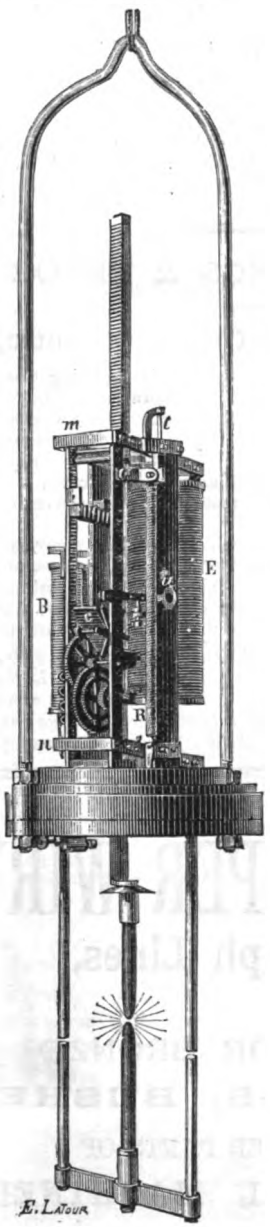

FIG. 1.

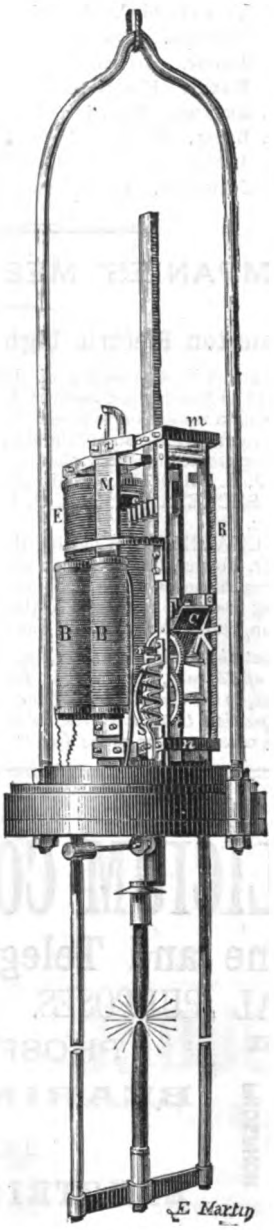

FIG. 2.

to the main circuit. The soft iron core lies almost entirely within the solenoid, and is attached to one end of an oscillating frame, *m*. To the other end of the same frame are attached two vertical bars, which carry a series of toothed wheels, and which are joined at the bottom to a second oscillating frame, *n*. The clockwork, therefore, participates in the movements of the two vertical bars of the parallelogram *m n*, but the principal wheel engages with the rack to which the positive carbon is connected. The spring R balances the weight of the soft iron core, which tends to lift the clockwork.

When the lamp is out of circuit the core keeps the arrangement of wheels in its highest position, and the arm *a* (Fig. 1) brakes the star-wheel, which is on the same spindle as the fly-wheel *c*. The rack cannot, therefore, descend, and the carbons are apart. When the lamp is switched in, the current traverses the solenoid, and the core, attracted upwards, lowers the other end of the parallelogram, and brings the carbons into contact. At the same instant the solenoid current becomes weak, the clockwork and the positive rod, therefore, lift and the arc is struck, When the arc becomes too long, the power of the solenoid increases and the upward movement of the core causes the part *m n* of the parallelogram to descend; the lever *a* (Fig. 1) meets a stop, and being lifted frees the star-wheel. The positive carbon then feeds down until the arc attains its normal length, when the lifting of the clockwork brings the brake again into play.

When the carbons are nearly consumed the arc is broken, and the current is shunted through the coils of the electro magnet BB (Fig. 2), which are brought into circuit by the carbon-holder meeting a special metal contact arranged underneath the base of the lamp. The electro magnet BB now attracts its armature, which is fixed to the oscillating frame; the end *m n* is pulled down, and the spring S (Fig. 2) is pressed against the base plate, short circuiting the lamp. To ensure smooth working there is an air dash-pot established within the solenoid core itself, the piston of which is fixed at *t*.

LEGAL INTELLIGENCE.

The Queen v. Redman.

This was a case heard before Mr. Baron Huddleston and Mr. Justice Mathew, on Monday, under the Metropolitan Building Act, in which a rule was applied for against the district surveyor of Deptford that he should show cause why he should not be ordered to put in force the provisions of the Act. It appeared that the London Electric Supply Company, whose premises were next to the General Steam Navigation Company's premises, although they had deposited plans which were in accordance with the schedule to the Act, had erected a wall which did not comply with the conditions of the statute, not having proper footings, &c. The building operations were finished in March, 1888, and no steps were taken until February, 1889, to enforce the Act, as the contraventions of the Act were only discovered by digging in November, 1888. The district surveyor had refused to put the Act in force.

The Attorney-General (Sir Richard Webster, Q.C.), with him Mr. Cripps, appeared for the rule; Mr. Finlay, Q.C, and Mr. Bremner appeared to show cause; Mr. E. Harrison was for the London County Council.

Mr. FINLAY argued that the rule was discretionary, and that (1) there was too great a delay to justify a mandamus being issued; (2) that the plaintiffs should have proceeded under the clauses with reference to dangerous buildings; and (3) the plaintiffs had another remedy by action which they were enforcing in another Court.

The ATTORNEY-GENERAL argued that there had been no delay, because the work the Electric Company had done was done behind the back of the General Steam Navigation Company; that the non-compliance with the Act was only discovered some time after by digging, and that, though there might be a remedy as between the two companies as private corporations, such remedy did not debar their right to compel a public officer to perform his duty.

Mr. BARON HUDDLESTON gave judgment as follows:—It is clear that there has been no delay, since the work was done surreptitiously, and as soon as it was discovered by digging, proceedings were taken. The Act is for the protection of the public, and it is clear that the statutory requirements have not been complied with. Mandamus must go.

Mr. Justice MATHEW concurred.

COMPANIES' MEETINGS & REPORTS.

Taunton Electric Lighting Company (Limited).

An extraordinary meeting of the Taunton Electric Lighting Company was held on Monday last week, at the Castle Hotel, Taunton, for the purpose of passing a resolution to create 2,000 new shares of £5 each, necessitated by the increased demand of the electric light, to provide which new premises are being erected and new plant purchased.

Mr. J. H. BALE (Vice-Chairman of the Company) presided.

The SECRETARY (Mr. F. C. Bostock), read the notice convening the meeting.

The CHAIRMAN, in moving the first resolution, said he was very sorry that Mr. Fowler, the Chairman of the Board of Directors, was not present. The circumstances which had given rise to the necessity of calling this meeting would be explained to them by their Managing Director, Mr. Massingham, and all he would do was to propose the following resolution :—

"*That the capital of the Company be increased by creating 2,000 new shares of £5 each, and that the Directors be empowered to offer, in the first instance, to the shareholders of the Company willing to accept the same, and in proportion to their several holdings, and subject thereto to issue and allot in such other manner as the Directors may think expedient, all or any of such*

new shares, at such time or times, and at any premium, and generally on such terms and conditions in all respects as the Directors may determine."

Mr. H. G. MASSINGHAM, in seconding the adoption of the report, said he was extremely pleased that the finances of the Company necessitated such a resolution being passed. It was four years ago since the electric light was introduced into Taunton. They had then only one dynamo. Now they possessed six dynamos, and their works would hold no more, so that at the present time they were obliged to refuse further custom. They had been in that position for some months now, and the Directors had to choose between two alternatives—to refuse custom or increase their works. They had decided to adopt the latter alternative, and as their present works were not capable of extension the Directors had purchased a plot of land, which had been known as St. James's Vicarage, and upon that they were building an entirely new depôt. When completed he thought it would be a model depôt, and something worth showing those numerous deputations who, during the past three or four years, had visited Taunton from all parts of the United Kingdom. He was very pleased to say that as a result of the visits they had received, and especially of the visits of electrical engineers, the electric light industry had received a great impetus throughout the country. Amongst the gentlemen who had been to Taunton to see the light he might mention the late President of the British Association, Sir F. Bramwell, who had been asked to advise the Corporation of Bedford as to the advisability of introducing the electric light in the town. Previous to his visit a deputation from the Corporation came to Taunton, and they were so pleased that they asked Sir Frederick Bramwell to see the Taunton depôt too. Major Waller, secretary of the London Electric Supply Corporation, who were building huge works at Deptford, had also been down to inspect the works, and practically all that had been done in London was an imitation of what they had successfully accomplished in Taunton; but Taunton had done it on a small scale, and the Londoners were going to do it on a more gigantic scale. He also referred to the report of Mr. Preece, who was advising Bristol, who, although largely interested in gas, had no fear that electricity would do away with gas. He practically supported their experience that the introduction of the electric light was no morelikely to do away with the use of gas than the steam engine had done away with horses, which many predicted would be the case when the steam engine was first introduced. Mr. Preece also further advised the Corporation of Bristol to adopt the same system of distribution which had been so successfully introduced in Taunton, Exeter, and Bath. These three towns out of the whole of the United Kingdom he specially mentioned, and it was extremely gratifying to him (Mr. Massingham) personally because he happened to be associated with the introduction of the electric light in those places. In Exeter he held a similar position to that he held in Taunton, while in the case of Bath the electric light works were his own property. The Corporation of Bath had given him a seven years' contract for the lighting of 50 of the principal streets, squares, and crescents on the Thomson-Houston system. It was the largest public electric lighting contract ever yet attempted in this country. Mr. Massingham then read extracts from Taunton, Bath, and Exeter papers to show the growing appreciation of the light. With regard to Bath it was reported that the Grand Pump Room Hotel was to be lit throughout by electricity, and the work had already commenced. So they saw that in the West of England the electric light was progressing very fairly indeed. At the present time the share capital of the Taunton Company was £9,125, and in addition to that they had £3,000 in debentures. When the Directors last had the pleasure of meeting them their share capital was a little under £5,000. They then offered shares to the public, and the whole of them had been taken up, and they were in this position now—with the exception of £875, that was practically all they could issue, and he might mention that they had applications for more than that amount already. They were now obliged to call this meeting for the purpose of increasing the nominal capital of the Company, so that they might be in a position to issue shares when applied for to enable them to pay for the new depôt. Another thing he thought he ought to touch upon was the price. He found that the price at which the electric light was supplied in Taunton was lower than that charged in any other town in the United Kingdom, with the exception of Bath and Exeter, where it was the same. As far as he could ascertain, it was lower than had been charged anywhere on the Continent or in America. In fact, he believed it was the lowest in price of any place in the world. The average price of the electric light in London was 100 per cent. more than was charged in Taunton, even in competition with those large companies with their enormous capital and greater power. He found, too, that in the case of the Eastbourne, Brighton and Hastings Company the average charges were 200 per cent. more than they were charging in Taunton, so that there was no disguising the fact that Tauntonians were in a position to enjoy one of the greatest products of science at a price that no other community in this country could possibly command, and he sincerely hoped when they put down the new plant they should have a large acquisition of customers.

Mr. W. POTTER supported the resolution, and said their nominal share capital at first was £10,000, and of that sum they only called up £5,000, that modest sum being deemed sufficient for the requirements of the moment, but as the demand for the light increased, and they knew as well as he did how rapid had been that demand, it was necessary to call up the additional £5,000, and the ready way in which that call was responded to was not only very satisfactory to the Directors, but it showed in the most conclusive manner how, during the two years of its existence, the Company had grown in public favour, and the confidence it inspired in the public mind as a safe and profitable investment. The Directors in asking them that night to increase their share capital to £20,000, and in going to the public and asking them to subscribe, thought they could do so with confidence from the success they had achieved in the past.

The resolution was put to the meeting and carried unanimously.

A vote of thanks to the Chairman was given, on the motion of Mr. WAKEFIELD, seconded by Mr. A. STEEVENS, and the proceedings terminated.

CITY NOTES, &c.

BIRMINGHAM SAFE DEPOSIT COMPANY (LIMITED).—This company was registered on the 18th inst., with a capital of £20,000, in £5 shares, to carry on the business of a safe deposit company, and also of gas, electrical, and mechanical engineers. Registered without special articles.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended October 25 amounted to £4,191.

ELECTRICAL ACCESSORIES COMPANY.—This company has purchased the works and business of Mr. S. Atkins, of Hockley Hill, Birmingham. A specialty of their manufactures will be the Atkins Universal Shade Carrier.

ELECTRICAL AUTOMATIC DELIVERY BOX COMPANY.—Mr. F. G. Painter (of the firm of Tribe, Clarke, Painter, and Co., Moorgate-street) has been appointed official liquidator of this company.

INDO-EUROPEAN TELEGRAPH COMPANY.—The Board of Directors of this Company have declared an interim dividend for the half-year ended the 30th June last, at the rate of 5 per cent per annum, free of income tax, payable on and after the 1st November.

THE NATIONAL ELECTRIC SUPPLY COMPANY (LIMITED).—This Company has been formed with a capital of £100,000, in 19,900 ordinary shares and 100 founders' shares of £5 each, to carry on in England or elsewhere the trade and business of electric lighting and the supply of electric force and motive power for communication or locomotion. First directors shall be Charles Herbert Cobbold, Dan Rylands, Thomas Robinson, and Walter Emmett, and three others may be added to the board. Qualification, 50 shares, or £250 stock. Remuneration, £100 per annum each (chairman £200), and further by vote in general meeting. Registered by S. Learoyd and James, solicitors for the Company, 12, Coleman-street.

LLANELLY ELECTRIC LIGHT AND POWER COMPANY.—This company has been registered with a capital of £15,000, in £1 shares. Objects: To generate, produce, and distribute electricity for the purpose of lighting streets and public and private buildings, and for supplying electric motive power.

NATIONAL TELEPHONE COMPANY.—The Committee of the Stock Exchange have ordered shares Nos. 1 to 386,875 of the National Telephone Company to be quoted in lieu of those of the United Telephone Company.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—At a meeting of the Board of Directors of this Company held yesterday it was decided that, after placing £7,500 to the renewal fund, and £5,600 to the Debenture redemption fund, the Directors would recommend at the forthcoming meeting a dividend of 6s. per share (free of income-tax), being at the rate of £4 per cent. per annum for the six months ended 30th June last. The transfer books will be closed from the 6th to the 10th November, both days inclusive.—The traffic receipts for the week ended October 25, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,739.

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

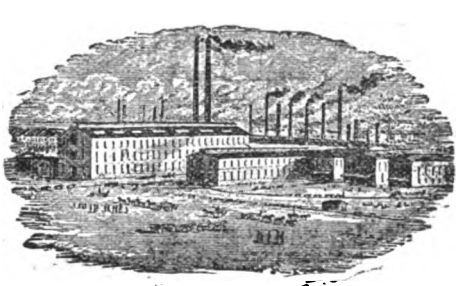
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Wilson Hartnell.
Johnson & Phillips.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

MANVILLE & MADGEN, *Managing Directors.*
